do his paintings. A characteristic example is the statuette of a "Faun" (National Gallery, Berlin; replicas Kunsthalle, Hamburg, and National Museum, Budapest). One of the original leaders in art Secession (q.v.), Stuck at first met with much hostility, but later came to be considered one of the great leaders in German art. He received the highest awards, became a member of the principal German academic and secessionist societies, a knight of several German and foreign orders, and professor in the Munich Academy. His art captivates by the power and originality of its design and by its strong decorative qualities. Although the color lacks charm, it is quite appropriate to the weird character of his subjects. His drawings are of great power and his etchings important. Consult O. J. Bierbaum, "Stuck," in *Künstler-Monographien*, vol. xlii (Bielefeld, 1899). For his drawings see H. W. Singer, *Franz Stuck: Zeichnungen* (Leipzig, 1912), and for reproductions of his entire works the large publication by Hanfstängl (Munich, 1909).

**STUCK**, HUDSON (1863-1920). An American Protestant Episcopal clergyman and alpinist. He was born in England, but came to the United States in 1885, and in 1892 graduated from the theological department of the University of the South (D.D., 1907). Ordained a deacon and priest, he was rector of Grace Church, Cuero, Tex., in 1892-94, then served as dean of St. Matthew's Cathedral at Dallas, Tex., until 1904, and thereafter was archdeacon of the Yukon. Archdeacon Stuck was a deputy to the General Convention of his church in 1898, 1901, and 1913. On June 7, 1913, with three companions, Harry Karstens, Robert G. Tatum, and Walter Harper, he reached the summit of the highest peak of the Denali or Mount McKinley group in Alaska (c.20,500 ft.), his party being the first to perform this feat. Preliminary preparations for the climb were made in the winter of 1912-13, the ascent from the lowest base camp was begun April 11, and on May 3 the party had established its immediate climbing base at the head of the Muldrow glacier. On North Peak (c.20,000 ft.) a flagstaff left by the Pioneer Expedition in 1910 was found. On South Peak, the ultimate goal, the corrected mercurial barometer reading was 13.6 inches and water boiled at 174.9°. In recognition of his achievement, Archdeacon Stuck was elected a fellow of the Royal Geographical Society, London. Consult his *Ascent of Denali (Mount McKinley)* (New York, 1914). He published also *Ten Thousand Miles with a Dog-Sled* (1914).

**STÜCKELBERG**, shtuk'el-bërk, ERNST (1831-1903). A Swiss genre and historical painter. He was born in Basel, and studied in Bern under Dietler, and in Antwerp, Paris, Italy, and Munich, where he won a gold medal in 1869. His most important work is the frescoes in Tell's Chapel on Lake Lucerne (1878-87). They are well composed and poetic in conception, but hard in color. He also painted a symbolic fresco in the Basel Gallery; historical pictures, such as "A Helvetic Sacrifice" and "Earthquake in Basel" (Basel Museum); Italian scenes, and serious genre scenes, mostly of child life. These include "The Marionettes" (Basel) and "Youthful Love" (Cologne).

**STUCKENBERG**, stuk'en-bërg, JOHN HENRY WILBURN (1835-1903). An American Lutheran clergyman and author, born at Bramsche, Hanover. He emigrated to America with his parents

in his youth and settled in the West, graduated from Wittenberg College, Ohio, in 1857, and studied in the universities of Halle, Göttingen, Berlin, and Tübingen. Coming back to America, he was ordained a Lutheran minister and held pastoral charges in Pennsylvania and Iowa. In 1873 he was made professor of theology in Wittenberg College, but in 1880 went to Germany again, where he became pastor of the American Chapel in Berlin. After many years in this service he returned to America and took up his residence in Cambridge, Mass. His later years were largely devoted to the study of theoretical sociology, to which he made valuable contributions. His chief works are: *History of the Augsburg Confession* (1869); *Christian Sociology* (1880); *Life of Immanuel Kant* (1882); *Sociology* (1903).

**STUCLEY**, stük'li, or **STUKELY**, THOMAS (c.1525-78). An English adventurer. About 1552 he went to France, and there gained the favor of the King, Henry II, who sent him to England to obtain information to be used in a projected attack on Calais. Stucley, however, revealed the nature of his mission to the English government, but, instead of being rewarded, was imprisoned in the Tower. In 1563, with the patronage of Queen Elizabeth, he pretended to join Ribault's colonization expedition to Florida, but instead turned privateer, and seized many French, Spanish, and Portuguese vessels. After two years of this life he was seized at Cork, but apparently was not brought to trial. For several years afterward he was employed in Ireland, but, having intrigued with Spanish agents, he ultimately fled to Spain. In 1571 Stucley commanded three vessels at the battle of Lepanto, and seven years later, while in the service of Sebastian of Portugal, was killed in the battle of Alcázar in Morocco. He became the hero of numerous ballads and plays. One of these, *The Famous History of the Life and Death of Captain Thomas Stukely*, was printed "as it hath been acted," in London in 1605. It was reprinted in Richard Simpson's *School of Shakespeare* (1878), with a biography of Stucley prefixed.

**STUDBOOK**. A genealogical record of blooded stock. The British Studbook for horses is the oldest in existence and was first commenced in 1791. All the facts that are in existence regarding the evolution through systematic breeding of the modern horse is obtained through the British Studbook. There are records for cattle and dogs in America and England.

**STUDDING-SAIL TACK BEND**. See **KNOTTING AND SPLICING**.

**STUDER**, shtōō'dēr, BERNHARD (1794-1887). A Swiss geologist, born at Büren, Canton of Bern. He studied at Bern, Göttingen, and Paris, and in 1825 was made professor of mineralogy in the Bern Academy, later becoming professor in the University of Bern, which he helped to establish and where he labored continuously until 1873. Some of the more important of his works are: *Beiträge zu einer Monographie der Molasse* (1825); *Geologie der westlichen Schweizeralpen* (1834); *Lehrbuch der physikalischen Geographie und Geologie* (1844-47); *Geologie der Schweiz* (1851-53); *Zur Geologie der Berner Alpen* (1866).

**STUDNICZKA**, stōōd-nits'kà, FRANZ (1860-). An Austrian classical scholar, born at Jaslo. He studied at the universities of Prague

and Vienna. In 1889 he became professor of classical archaeology at Freiburg, in 1896 at Leipzig. Later he became director of the Archaeological Institute of the University of Leipzig. His publications, consisting almost wholly of articles in the learned periodicals, include: *Kyrene, eine altgriechische Göttin* (1890); "Tropæum Trajani," in *Abhandlungen der Sachsischen Gesellschaft der Wissenschaften*, vol. xxii (1904); "Kalamis," (ib., vol. xxv, 1907); "Ara Pacis" (ib., vol. xxvii, 1909); "Symposion Ptolomaios II" (ib., vol. xxx, 1913).

**STUHLMANN**, shtōōl'mán, FRANZ (1863-). A German zoologist and African explorer, born in Hamburg. After studying at Tübingen and Freiburg, he went to East Africa in 1888, and during the revolt of the Arabs in 1890 entered the German corps of defense as a lieutenant, and was severely wounded at Mlembule. After his recovery he joined the expedition of Emin Pasha to the lake region, was sent ahead from Undussuma to Lake Victoria, and reached the coast in July, 1892, at Bagamoyo, whence he returned to Germany with valuable cartographic material and rich collections, to which he added copiously on another trip to German East Africa, undertaken in 1893-94 by order of the government. In 1908-10 he was secretary of the Colonial Institute in Hamburg. He published *Zoologische Ergebnisse einer in die Küstengebiete von Ostafrika unternommenen Reise 1888-90* (1893-1901); *Mit Emin Pascha ins Herz von Afrika* (1894); *Beiträge zur Kulturgeschichte von Ostafrika* (1909); etc.

**STUHLWEISSENBERG**, shtōōl'vis'en-burk (Hung. *Székes-Fehérvár*). A royal free city, capital of the county of the same name, Hungary, 35 miles southwest of Budapest (Map: Hungary, F 3). The episcopal palace and the cathedral are noteworthy edifices. The manufactures of woollens, silks, and knives are extensive and the agricultural interests prominent. Stuhlweissenburg is the *Alba Regia* of the Romans. From the eleventh to the sixteenth century the kings of Hungary were crowned there; afterward the ceremonial took place at Pressburg. The city was held by the Turks from 1543 to 1688, with the exception of the period 1601-02. Pop., 1900, 32,167; 1910, 36,625.

**STUKELY**, THOMAS. See **STUCLEY**, THOMAS. **STUKELY**, stük'li, WILLIAM (1687-1765). An English antiquary, born at Holbeach, Lincolnshire. He graduated at Bennet (Corpus Christi) College, Cambridge, in 1708. With Roger Gales he made long antiquarian tours in various parts of England. Among his many published works are: *An Account of a Roman Temple and Other Antiquities, near Graham's Dike in Scotland* (1720); *Itinerarium Curiosum* (1724; 2d ed., 1776); *Stonchenge* (1740); *Abury, a Temple of the British Druids* (1743); *Palaographia Britannica* (1743-52); *The Philosophy of Earthquakes* (1750; 3d ed., 1756); *The Medallie History of Marcus Aurelius Valerius Caracausius* (1757-59).

**STÜLER**, shtul'ér, FRIEDRICH AUGUST (1800-65). A German architect, born in Mülhausen, Thuringia. He studied in Berlin and in France and Italy. Appointed court inspector of buildings at Berlin in 1830, he was two years later put at the head of the architectural commission of the Royal Palace. His principal buildings include the New Museum (1843-55), several churches, and parts of the Royal Palace in Berlin, the Academy of Sciences at Budapest, the

National Museum of Stockholm (1850-66), the Museum at Cologne (1855-61), the reconstructed Winter Palace at St. Petersburg, the University at Königsberg (1844-63), and the reconstruction of the Stolzenfels Castle and the Hohenzollern Castle (1850-67).

**STULL TIMBERING.** See MINING.

**STUMM-HALBERG**, shtym, KARL FERDINAND, BARON VON (1836-1901). A German manufacturer and political leader, born in Saarbrücken. He studied in Bonn and Berlin, and in 1858 became the head of the family firm which had for many years owned the great ironworks at Neunkirchen. He was a member of the Prussian Chamber from 1867 till 1870, and of the Reichstag from 1867 till 1881 and from 1889 till his death, in 1901, and was one of the founders of the German Reichspartei. In 1882 he became a member of the Prussian House of Lords and was created Baron in 1888. Over his thousands of workmen he exercised a paternalistic rule, and furnished them with hospitals, technical schools, a library, model dwellings, and other advantages. He was bitterly hostile to Socialism.

**STUMPF**, shtympf, CARL (1848- ). A German psychologist and philosopher, born at Wiesentheid, Bavaria. He studied at Würzburg and Göttingen, being especially influenced by the teachings of F. Brentano and R. H. Lotze. After becoming privatdocent at Göttingen in 1870, he was appointed to the chair of philosophy successively at Würzburg (1873), Prague (1879), Halle (1884), Munich (1889), and Berlin (1894), where he instituted the psychological seminar. In 1895 he became a member of the Prussian Academy of Sciences, and in 1907-08 was rector of Berlin University. His publications include numerous monographs upon psychology, æsthetics, ethnology, epistemology, and especially upon psychological acoustics. They comprise: *Ueber den psychologischen Ursprung der Raumvorstellung* (1873); *Tonpsychologie* (1883-90); *Tafeln zur Geschichte der Philosophie* (3d ed., 1910); *Psychologie und Erkenntnistheorie* (1891); *Beiträge zur Akustik und Musikwissenschaft* (1908-15); *Philosophische Reden und Vorträge* (1910); *Die Anfänge der Musik* (1911). Stumpf is best known by his contributions to the psychological study of sensations of tone and their use in music, though his later philosophical writings attracted widespread attention.

**STUNDISTS**, shtyn'dists (from Ger. *Stunde*, hour, lesson; so called from their meetings to read the Bible). A Russian sect of German origin. It has gained many converts among the peasants since 1870, and has attracted the hostile attention of the government. The Stundists bear some resemblance to the Baptists, give to the Sacrament a purely symbolic interpretation, and hold communistic views concerning property. They are most numerous in Little Russia and Bessarabia. Consult A. F. Heard, *The Russian Church and Russian Dissent* (London, 1887), and H. Dalton, *Der Stundismus in Russland* (Gütersloh, 1896).

**STUPA**, stōō'pā. A form of Buddhist architecture in India. See TOPE.

**STUPART**, ROBERT FREDERIC (1857- ). A Canadian meteorologist. He was born near Toronto, Ontario, and was educated at Upper Canada College. In 1872 he entered the Canadian meteorological service and for some years was senior inspector and probability officer at

the Toronto Magnetic Observatory. In 1884-85 he went to Hudson Strait with the expedition sent to report on the navigation of the strait, and was in charge of the chief observation station there. In 1894 he was appointed superintendent and director of the meteorological service of the Dominion and of the Magnetic Observatory, Toronto. He was president of the Royal Astronomical Society of Canada in 1902-03 and of the Canadian Institute in 1906-07.

**STURDEE**, stūr'dē, SIR FREDERICK CHARLES DOVETON (1859-1925). A British naval officer. He entered the navy in 1871 and early saw service in Egypt. In 1890-1902 he was assistant director of naval intelligence. Subsequently he served as chief of staff of the Mediterranean fleet (1905-07) and of the Channel fleet (1907). As rear admiral he commanded the Third Cruiser Squadron in 1912 and the Second Cruiser Squadron in 1912-13. Promoted vice admiral in the latter year, in 1914 he became chief of the war staff at the Admiralty. On Nov. 1, 1914, the British warships *Monmouth* and *Good Hope*, part of a squadron under command of Sir Christopher Cradock, were sunk in an action off the Chilean coast by a German squadron under Admiral von Spee. To avenge this defeat the Admiralty placed Sturdee in command of a fleet which on December 8 attacked and destroyed the German squadron (except for the *Dresden*) off the Falkland Islands in the South Atlantic, sinking the cruisers *Scharnhorst*, *Gneisenau*, *Leipzig*, and *Nürnberg*. The *Dresden* was afterward sunk in Chilean waters. Von Spee was lost with his flagship, the *Scharnhorst*. Sturdee received the K.C.B. in 1913 and was made Baronet in 1916.

**STURDY**. A parasitic disease of sheep. See GRD.

**STURDZA**, stōōrd'zā, ALEXANDER (1791-1854). A Moldavian publicist and diplomat, who was educated in Germany but was afterward in the diplomatic service of Russia. His *Mémoire sur l'état actuel de l'Allemagne*, published at the Congress of Aix-la-Chapelle in 1818, by order of Alexander I, aroused great indignation in Germany because of the unbecoming levity with which its author arraigned the German national character and branded the universities as hotbeds of the revolutionary spirit and of atheism. In 1819 Sturdza settled at Dresden, married a daughter of Hufeland, and subsequently retired to his estate of Mansyrs, Bessarabia, and later to Odessa. His writings include, besides the work mentioned: *La Grèce en 1821* (1822); a biography of Hufeland (1837); and *Oeuvres posthumes religieuses, historiques, philosophiques et littéraires* (1858-61).

**STURDZA**, DEMETER (1833- ). A Rumanian statesman and author. He studied political science at Munich, Göttingen, Bonn, and Berlin, became Minister of Public Instruction in 1859, and was one of the most zealous promoters of the overthrow of Cuza and the election of Prince Charles of Hohenzollern in 1866. In the cabinet of Bratianu (1876-88) he held repeatedly ministerial posts, and in 1895-96 presided over a National-Liberal ministry. Again in 1897-99, in 1901-04, and in 1907-09 he held the premiership, together with the portfolio of foreign affairs. He wrote: *Uebersicht der Münzen und Medaillen des Fürstentums Rumänien* (1874); *La marche progressive de la Russie sur le Danube* (1878); *Europa, Russia, Romania* (1888); *La question des portes de fer et des*

*cataractes du Danube* (1899); *Charles I, roi de Roumanie* (1899 et seq.).

**STURE**, stŭr'e. A noble family of Sweden which played a very prominent part in the affairs of that country in the fifteenth and sixteenth centuries and became extinct in 1616. Its chief representatives were: (1) **STEN STURE the Elder** (died 1503). He was a son of Gustaf Sture and the nephew of King Charles VIII, on whose death, in 1470, he became Regent of Sweden, in spite of the opposition of the Swedish nobility, who supported the claims of Christian I of Denmark. He defeated the Danish King in the battle of Brunkeberg, near Stockholm (1471). He introduced printing, and founded the University of Upsala (1477). In 1497 he was forced to resign his place to John of Denmark, but regained power in 1501 and ruled till his death (1503). He was followed by (2) **STEN STURE the Younger**, a kinsman, who, aided by the peasantry, foiled the plan of the nobles to place Trolle, one of their own number, in power, gained the regency for himself, twice defeated (1517 and 1518) Gustaf Sture, Archbishop of Upsala, whom he had deposed in 1517, and was himself defeated and mortally wounded in a battle against Christian II of Denmark at Bogesund in 1520. His widow, Christina Gyllenstierna, held Stockholm until the new King guaranteed a constitutional government.

**STURGE**, stŭrj, **JOSEPH** (1793-1859). An English philanthropist and abolitionist, born in Gloucestershire. About 1818 he became a corn factor at Bewdley, and in 1822 moved to Birmingham, where he was chosen alderman. He toured the West Indies; published *The West Indies in 1837* (1837), to show the evils of slavery; contributed largely to the work to benefit negroes freed by English law; and in 1841 toured the United States with John Greenleaf Whittier to investigate slavery there. In 1842 he joined the Chartists, but was defeated in his candidacy for Parliament. Subsequently he gave much time to promoting international arbitration.

**STURGEON** (OF., Fr. *esturgeon*, Sp. *esturión*, It. *storione*, from ML. *sturgio*, *sturio*, sturgeon). A large fresh-water fish of the ganoid family *Acipenseridae*. Sturgeons have an elongated, subcylindrical body, armed with five rows of bony plates or bucklers, each bearing a median keel. The head is covered by bony plates joined by sutures. The snout is produced; the mouth is inferior, opening on the under side of the head,

female producing from two to three million eggs, constituting from a fifth to a third of its entire weight. They feed on small animals and plants, which they suck into the mouth. The common sturgeon (*Acipenser sturio*), of the coasts and rivers of Europe and northeastern America, has been known to weigh 500 pounds. The lake or rock sturgeon (*Acipenser rubi-*

SKULL OF A STURGEON WITH MEMBRANE BONES REMOVED.

a, rostrum; b, nasal capsule, c, eye socket, d, foramina for spinal nerves, e, notochord, g, quadrate bone; h, hyomandibular bone; i, mandible, j, basibranchials; k, ribs; l, hyoid bone; I, II, III, IV, V, branchial arches.

*cundus*), once very abundant in the Great Lakes and the Mississippi valley, attains a weight of 200 pounds, but the average is much less. Its sides are reddish, often with irregular blackish spots. Very peculiar in its prolonged paddle-shaped snout is the "shovelnose" or "white" sturgeon (*Scaphirhynchus platyrhynchus*), pale olive in color and about 5 feet long. It is a denizen of the Western and Southern States. Similar species occur in Asia. The largest of American sturgeons is that of the Pacific coast (*Acipenser transmontanus*) called "white" in comparison with the rare "green" sturgeon (*Acipenser medirostris*). The former weighs 300 to 600 pounds and is used as food, but the latter, nearly as large but olive green, is not eaten. The great Russian "beluga" or "huso" (*Acipenser huso*) is very large and has been known to become 20 to 25 feet long and to weigh 3000 pounds. This species, once abundant in the Danube, Volga, and other large rivers emptying into the Black and Caspian seas, has furnished mainly the salted roe called caviar (q.v.), though some comes from the small sterlet (*Acipenser ruthenus*) of the same region. The air bladder is also utilized for making isinglass.

Fossil sturgeon remains indistinguishable from the corresponding portions of the skeletons of modern species have been found in rocks as old as the Eocene. Earlier less specialized ancestral forms are *Chondrosteus* of the Jurassic and perhaps also the still older *Palæoniscus* of the Permian and *Cheirolepis* of the Upper Devonian. Consult authorities cited under FISH and FISH-ERIES. See CHEIROLEPIS; CHONDROSTEUS; PALÆONISCUS; and Plate of STURGEONS.

**STURGEON**, stŭr'jŭn, **WILLIAM** (1783-1850). An English electrician, born at Whittington, Lancashire. As early as 1823 he constructed a soft-iron electromagnet, and in 1830 described for the first time the process of amalgamating the zinc plate of a battery with mercury. In 1832 he constructed an electromagnetic rotary engine, the first contrivance by means of which any considerable mechanical force was developed by the electric current. Five years afterward he produced an electromagnetic coil for giving shocks. In 1836 he founded the first electrical journal, the *Annals of Electricity*.

A FOSSIL STURGEON.

protractile and without teeth. Just anterior to the mouth there are four barbels. The tail has the upper lobe much larger than the lower. There is a single dorsal fin, placed like the anal fin far back. They have a large air bladder, connected by a tube with the esophagus. About 25 species, in two genera, are recognized, all inhabitants of fresh waters and seas in northern regions. Most of the species are migratory and ascend streams to spawn, but some live permanently in fresh waters. They spawn in the spring and summer, and are prolific, a large

1. SHOVEL-NOSED STURGEON (*Scaphirhynchus platyrhynchus*).
2. PADDLE-FISH (*Polyodon spathula*), side view.
3. PADDLE-FISH, ventral view.
4. LAKE STURGEON (*Acipenser rubicundus*).
5. COMMON STURGEON (*Acipenser sturio*).
6. BOWFIN (*Amia calva*); in proportion to the other figures much enlarged.

Among his works are: *Experimental Researches in Electro-Magnetism, Galvanism, etc.* (1830); *Lectures on Electricity* (1842); *Twelve Lectures on Galvanism* (1843); *Scientific Researches* (1850).

**STURGEON BAY.** A city and the county seat of Door Co., Wis., 45 miles northeast of Green Bay, on a canal connecting Green Bay and Lake Michigan, and on the Ahnapee and Western Railroad (Map: Wisconsin, F 4). There are canning establishments, shipyards, stone quarries, and manufactories of boxes, beer, flour, foundry and machine-shop products, etc.; and extensive fruit-growing interests. The city has a State fish hatchery, a public library, Peninsula State Park, Indian burial grounds, and government lighthouses. Pop., 1900, 3372; 1910, 4262.

**STURGEON FALLS.** A town in the Nipissing District, Ontario, Canada, on Lake Nipissing and on the Canadian Pacific Railway (Map: Ontario, F 1). It is the starting point of tourists for French River and the western part of Lake Nipissing. Pop., 1901, 1418; 1911, 2199.

**STURGIS.** A city in St. Joseph Co., Mich., 36 miles south by east of Kalamazoo, on the Grand Rapids and Indiana and the Lake Shore and Michigan Southern railroads (Map: Michigan, D 7). It is of some industrial importance, the leading manufactures being furniture, steel gocarats, stair and drapery rods, plumbers' brass goods, shears, garments, farm tanks, corn poppers, and foundry and machine-shop products. Pop., 1900, 2465; 1910, 3635.

**STURGIS, RICHARD CLIPSTON** (1860- ). An American architect, born in Boston. He graduated from Harvard (1881). After studying architecture in London, he began practice in Boston, where he succeeded to the business of John H. Sturgis in 1887. He was architect of the Franklin Union, Boston; Brookline (Mass.) Public Library; First National Bank, Boston; Perkins Institution for the Blind; the cathedral at Manila, Philippine Islands; and was one of the advisory architects of the new Museum of Fine Arts, Boston. Sturgis served as president of the Boston Society of Architects in 1910-14 and of the American Institute of Architects in 1914-15.

**STURGIS, RUSSELL** (1836-1909). An American architect and author, born in Baltimore. He studied architecture in New York and in Europe, and practiced his profession from 1865 till 1880. Within this period he designed Battell Chapel, Farnam Hall, Durfee Hall, and Lawrence Hall of Yale College; the Farmers' and Mechanics' Bank at Albany; the Homœopathic Medical College and Flower Hospital in New York. In 1878 he became professor of architecture and the arts of design in the College of the City of New York. He was an industrious writer, contributing to a large number of dictionaries, encyclopædias, and periodicals, and ranked as one of the foremost American scholars in the history of architecture and decoration. His writings include: *Manual of the Jarves Collection of Early Italian Pictures* (1868); *European Architecture: An Historical Study* (1896); *Annotated Bibliography of Fine Art* (1897); *How to Judge Architecture* (6th ed., 1903); *Appreciation of Sculpture* (1904); *The Artist's Way of Working in the Various Handicrafts and Arts of Design* (1905; 2d ed., 1910); *The Appreciation of Pictures* (1905); *A History of Architecture* (vols. i-ii, 1906-09; completed, vols. iii-iv, by A. L. Frothingham, Jr., 1915).

VOL. XXI.—40

He contributed to the first edition of the NEW INTERNATIONAL ENCYCLOPEDIA and was editor and chief author of a *Dictionary of Architecture and Building* (1901-02).

**STURGIS, SAMUEL DAVIS** (1822-89). An American soldier, born at Shippensburg, Pa. He graduated at West Point in 1846, served through the Mexican War, and was a prisoner at Buena Vista. In the Civil War he was obliged to abandon Fort Smith, Ark., of which he was commandant, but saved his command. As major of the Fourth Cavalry he served in 1861 under General Lyon, and succeeded to his command at Wilson's Creek (q.v.). Sturgis was prominent at South Mountain, Antietam, Fredericksburg, and commanded the cavalry of the Department of the Ohio in 1863-64, capturing Vance and routing Martin's Confederate cavalry. Later he took part in an expedition against Forrest. In 1869 he became colonel of the Seventh Cavalry. He was Governor of the Soldiers' Home near Washington (1881-85), and in 1886 he retired.

**STURLUSON, SNORRI.** See SNORRI STURLUSON.

**STURM, shturm, AUGUST** (1852- ). A German poet, son of Julius Sturm. He was born at Göschütz. He studied at Jena, Leipzig, and Berlin, first theology, afterward law, which he practiced at Naumburg after 1884. In 1880-82 he had been a government official at Rudolstadt and then for two years had lived in Berlin. Besides the epic poems, *Merlin* (1892), *Kaiser Friedrich der Edle* (1896), *König Laurins Rosengarten* (1897), and *Der König von Babel* (1902), he published *Hohenzollernsagen, Balladen* (1898); the lyrics *Auf Flügeln des Gesanges* (1883; 2d ed., 1909); *Lied und Leben* (1889); *Siegfrieds Tod* (1904); several dramas, notably *Die Liebesburg* (1910), and prose sketches, *Sylter Skizzen* (1887); also *Revision der gemeinrechtlichen Lehre vom Wohnheitsrecht* (1900) and other juridical works.

**STURM, sturm, JACQUES CHARLES FRANÇOIS** (1803-55). A French mathematician, born at Geneva, Switzerland. He was educated at the Academy of Geneva, and in 1827, with his friend Colladon, took the *Grand prix de mathématiques* for the best memoir on the compression of liquids. The famous theorem that bears his name was discovered in 1829. A statement of the results secured by this theorem requires the definition of Sturm's functions: If  $f(x) = 0$  is freed from equal roots, and  $f(x)$  be divided by  $f'(x)$  (the derivative of  $f(x)$ ) and the last divisor by the last remainder, changing the sign of each remainder before dividing by it, until a remainder independent of  $x$  is obtained, or else a remainder which cannot change its sign, then  $f(x)$ ,  $f'(x)$ , and the successive remainders, constitute Sturm's functions. The theorem asserts that if, as  $x$  increases,  $f(x)$  passes through the value zero, Sturm's functions lose one change of sign; if any other of Sturm's functions vanishes, there is neither loss nor gain in the number of changes of sign; the number of roots of  $f(x) = 0$  between  $a$  and  $b$  is equal to the difference in the number of changes of sign in Sturm's functions, when  $x = a$  and when  $x = b$ . In 1838 Sturm began teaching in the Ecole Polytechnique, and two years later was elected to the chair made vacant by the death of Poisson.

**STURM, shturm, or STURMIUS, JOHANNES** (1507-89). A German educator, born near

Cologne, and educated at Leyden and Louvain. In 1537 he organized the Strassburg Gymnasium, which he directed for 43 years. Through his system of gradation of classes, and classification of literary material for use in schools, he shaped the practice of secondary education in German schools, and exercised considerable influence on the Jesuit system of education.

**STURM, JULIUS** (1816-96). A German poet, born at Küstritz, Reuss. After studying theology at Jena (1837-41), he was private tutor to the hereditary prince Henry XIV of Reuss, then pastor at Göschütz, near Schleiz, in 1851-57, and at Küstritz from 1857 to 1885. He died at Leipzig. All his lyrics reveal him as a poet of deep religious sentiment and genuine national spirit. The religious poems are incorporated in the collections *Fromme Lieder*, three parts (1852; 1858; 1892; 12th ed., 1893 et seq.); *Zwei Rosen oder das Hohelied der Liebe* (1854); *Von der Pilgerfahrt* (1868); *Gott grüsse dich* (1876); *Dem Herrn mein Lied* (1884); *Palmen und Krone* (1888); and others; while the volumes with secular contents include: *Für das Haus* (1861); *Lieder und Bilder* (1870); *Kampf- und Siegesgedichte* (1870); *Spiegel der Zeit in Fabeln* (1872); *Kinderleben* (1877), illustrated by Ludwig Richter; *Immergrün* (1880); *Natur, Liebe, Vaterland* (1884); *In Freud und Leid* (1896). For his biography, consult Hepding (Giessen, 1896) and Hoffmann (Hamburg, 1898).

**STURM, RUDOLF** (1841- ). A German mathematician. He was born at Breslau, where he was educated at the university. He served as professor at the Technische Hochschule of Darmstadt in 1872-78, at the Akademie (now University) of Münster in 1878-92, and thenceforth as professor of mathematics at Breslau. His works include: *Synthetische Untersuchungen über Flächen 3. Ordnung* (1867); *Elemente der darstellenden Geometrie* (1874; 2d ed., 1900); *Das Gebilde ersten und zweiten Grades der Liniengeometrie in synthetischer Behandlung* (3 vols., 1892-96); *Die Lehre von den geometrischen Verwandtschaften* (4 vols., 1903-09); *Maxima und Minima in der elementarischen Geometrie* (1910).

**STURT, CHARLES** (1795-1869). An Australian explorer. He was born in Bengal, India, of English parents, was educated in England, entered the British army, and in 1825 went to New South Wales. In 1828 he headed an exploring expedition which penetrated the interior of Australia and discovered the Darling River. On a second journey (1829-30) he discovered the Murray River, which he descended to Lake Alexandrina. Another expedition in 1844 reached the centre of the continent. He held several high colonial positions. He became totally blind as a result of the hardships he had undergone, and returned in 1853 to England. There he died just before the date when he was to have received the K.C.M.G. He published *Two Expeditions into the Interior of Southern Australia 1828-31* (2 vols., 1834), and *Narrative of an Expedition into Central Australia in 1844-46* (2 vols., 1849). Consult N. G. Sturt, *Life of Charles Sturt* (London, 1899).

**STURZ, HELFERICH PETER** (1736-79). A German author, born at Darmstadt. He studied law (1753-58) at Jena, Giessen, and Göttingen, was appointed secretary in the department of foreign affairs at Copenhagen in 1764, soon after private secretary to Count Bern-

storff, and in 1768 went with the retinue of King Christian VII to England and France. Involved in Struensee's downfall in 1772, he was imprisoned and banished from Copenhagen, but appointed again to a position at Oldenburg in 1773, and died at Bremen. His title to the reputation as one of the most tasteful German prose writers is amply demonstrated by the exquisite *Briefe eines Reisenden* (1777), and his *Erinnerungen aus dem Leben des Grafen von Bernstorff*. Consult the biography by Max Koch (Munich, 1879).

**STUTTERING**. Imperfect action of the organs of articulation resulting in defective speech. See STAMMERING.

**STUTTGART**, stüt'gärt. The capital of the Kingdom of Württemberg, Germany, situated at an elevation of 890 feet (Map: Germany, C 4). Stuttgart occupies a delightful site surrounded by attractive suburbs and amid vine-clad heights. The pronounced adherence of its many fine architects to the Renaissance types explains the stately appearance of the city.

The spacious Königstrasse extends diagonally from southwest to northeast through the old or inner city and borders the majestic Schlossplatz—the centre of interest. Here rises the impressive King William column (1841), 93 feet high, embellished with allegorical figures. Here too are the splendid Königsbau, the palace of the Crown Prince, the Residenz-Schloss (palace), the royal theatre, and the royal stables. The fine statue of Schiller by Thorwaldsen, erected in 1839 by national subscription, is near by. Adjacent also is the striking Gothic Stiftskirche, begun in 1436. Southeast of the Old Palace is the palace of King William II, where the fine modern Neckarstrasse begins its course northeastward. In the immediate vicinity are housed the Württemberg archives and also the extensive and valuable natural-history collections of Stuttgart. The royal public library near at hand contains upward of 603,000 volumes, 5500 manuscripts, and many specimens of early printing. The library building holds also the museum of Württemberg antiquities, among which may be seen ceramics, weapons, and articles taken from ancient tumuli and lake dwellings. In the rear of the library is the large modern Palace of Justice. Between the library and the Residenz-Schloss stands a spacious and famous academy—the Karlsschule. Extending northeast from this vicinity and along the Neckarstrasse is the beautiful Schlossgarten. It embraces 200 acres, is 2 miles long, and is embellished with ponds, flower designs, and sculptures. Here are found the botanic gardens, the mint, and the notable Stuttgart museum of art with its collections of sculpture and painting. In the northwest section of the city stands the Technical High School (1386 students in 1913-14) facing the delightful Stadtgarten—one of the popular resorts. In the eastern part of Stuttgart is the immense new Liederhalle. In the vicinity of the Schlossplatz is found the modern Renaissance edifice of the Landesgewerbe Museum.

Among the prominent newer buildings in Stuttgart are the Queen Olga buildings, the new Town Hall, the Catholic church of St. Nicholas, and the Peace Church. The Uhlandshöhe and the Jägerhaus may be especially noted among the delightful resorts in the environs, as well as the royal country seat Wilhelma—a fine Moorish structure begun in 1842. Stuttgart has an art

academy, the Württemberg Art Union with a permanent exposition of modern masters, a technical high school with sections for architecture, civil, electrical, and mining engineering, chemistry and pharmacy, mathematics and natural science, an exposition of export products, the provincial industrial museum, a famous conservatory of music, an industrial and commercial library, and a veterinary school. It is the leading printing and book-publishing city of south Germany. Among its prominent manufactures are furniture, carriages, pianos, paper, leather, chemicals, colors, jewelry, bells, cigars, portmanteaus, chocolate, and especially cottons. Hops, cloth, and horses form special items in the trade. The city is governed by an overburgomaster, two advisers, and a council of some 24 members. Pop., 1900, 176,699; 1910, 286,218, mainly Protestants.

Stuttgart is first mentioned in 1229. It became the official capital of Württemberg in 1482; but it did not begin to improve and assume its present splendid proportions until about 1800. Consult: Klaiber, "Stuttgart," in *Europäische Wanderbilder* (Zurich, 1892); Widmann, *Wanderung durch Stuttgart und Umgebung* (Stuttgart, 1896).

**STUTTGART**, stüt'gärt. A city in Arkansas Co., Ark., 51 miles by rail southeast of Little Rock, on the St. Louis Southwestern and the Chicago, Rock Island and Pacific railroads. It makes large shipments of rice, oats, hay, and potatoes, and has rice mills, a handle factory, irrigating pump and screen works, an iron and brass foundry, and a saw mill. Pop., 1900, 1258; 1910, 2740.

**STUYVESANT**, stī've-sant, PETER (1592-1672). A Dutch Governor of New Netherland. He was born in Holland; early entered the military service of the Dutch in the West Indies, and in 1635 was made Director of the Colony of Curaçao. In 1646 the Dutch West India Company appointed him Director General of their colony in North America, New Netherland, where he soon gained the confidence of the colonists by his efficient administration and public improvements. He reconciled the Indians, made hostile by former unjust treatment, and arranged with the New England commissioners, in 1650, the boundaries between English and Dutch territories, but this was not entirely satisfactory to the Dutch colonists, who claimed he had ceded considerable territory rightfully theirs. A convention of delegates in 1653 demanded for the people a share in the appointment of local officers, but Stuyvesant ordered them to disperse, claiming his authority was not from the people, but from God and the Dutch West India Company. The protracted contentions of the Dutch and the Swedes near the Delaware River became more critical in 1654, when the Swedish Governor seized the fort built by the Dutch where Newcastle now stands. To end this trouble, Stuyvesant in 1655 with 600 men sailed up the Delaware, recaptured the fort, and established the Dutch authority over the entire territory. After nine years of comparative quiet, in 1664 a force of English soldiers arrived under Colonel Nicolls, who demanded a surrender of the government, on the ground that the whole territory had been given by royal charter to the Duke of York. The town at the time contained 1500 inhabitants and was defended by a stone fort and 20 cannon. Stuyvesant at first refused, but finding the people

anxious to exchange rulers, he yielded to the English demand. Stuyvesant, in 1665, reported personally to the authorities in Holland, but soon returned to New York, where he spent the remainder of his life, cultivating an extensive farm called the Bouverij (Bowery). He was buried where St. Mark's Church now stands, and the elaborately inscribed stone that covered his grave is built into the eastern wall of the church. Consult: E. B. O'Callahan, *The History of New Netherland* (New York, 1848); Bayard Tuckerman, *Peter Stuyvesant* (ib., 1893); J. S. C. Abbott, *Peter Stuyvesant* (ib., 1898).

**STYB**, or **STY** (formerly also *stian*, from A.S. *stigend*, stye, pres. part. of *stigan*, Ger. *steigen*, to rise), or **HORDEOLUM**. The popular name for an acute inflammation occurring around the follicle of an eyelash. It begins as a small, red, tense swelling, accompanied with considerable itching and a feeling of stiffness. In a few days pus forms; a yellowish point appears at the apex of the swelling; and when the cuticle gives way, pus and a small slough of connective tissue escape, after which there is a general remission of the symptoms, and the eyelid soon resumes its natural state.

The treatment includes the use of cold compresses of boric acid solution to abort the stye, hot ones to hasten suppuration, and evacuation of pus when it appears. Errors of refraction should be corrected and the general health improved in order to prevent recurrence.

**STYLISTE**. See **PILLAR SAINT**.

**STYLOBATE** (Lat. *stylobata*, *stylobates*, from Gk. *στυλος*, *stylos*, pillar + *βαίνειν*, *bainein*, to go). The topmost step of the crepidoma (*κρηπίδωμα*) or substructure of a Greek temple. This consists of the foundations, or stereobate, and the surrounding steps, usually three in number. On the topmost step, the true stylobate, rest the columns. The term is sometimes extended to apply to the whole series of steps.

**STYLOGRAPHIC PEN**. See **PEN**.

**STYLONURUS** (Neo-Lat., from Gk. *στυλον*, *stylon*, acc. sg. of *στυλος*, *stylos*, pillar + *οὐρά*, *oura*, tail). A gigantic extinct arachnid, allied to *Eurypterus*, with a body about 6 feet in length and with five pairs of legs, of which the posterior pairs are much elongated, and a long spine on the tail. It is found in the Silurian and Devonian of Scotland and of New York and Pennsylvania. See **ARTHROPODA**; **EURYPTERIDA**; **MEROSTOMATA**.

**STYMPHEALUS**. See **HERCULES**.

**STYPTIC**. An agent employed in surgery for the purpose of checking the flow of blood by application to the bleeding orifice or surface. See **BLEEDING**.

**STYRAX**. See **STORAX**.

**STYRIA**, stī'ri-ä (Ger. *Steiermark*). A duchy and crownland of Austria (Map: Austria, D 3). Its area is 8658 square miles. The northern part of Styria belongs to the region of the central Alps, while the southern part is occupied by the Styrian Alps. The plains are generally small, but there are a large number of fruitful valleys along the rivers, the chief of which are the Enns, Mur, Drave, and Save. There are many mountain lakes and mineral springs. Styria has a large proportion of productive land; the forests cover nearly one-half of the surface. Arable land (not including gardens, vineyards, and pastures) amounted in 1912 to 413,259 hectares, or nearly 19 per cent of the total area. Wheat, rye, corn, oats, and barley are leading crops. Hay is grown in large

quantities, and cattle-raising is very important, especially in upper Styria. Grapes and fruits are cultivated to a lesser extent. In mineral production Styria is one of the important crown-lands of Austria. In 1912 it produced 1,791,150 metric tons of iron ore (over 61 per cent of the total Austrian output), 3,091,397 tons of lignite, and 14,031 tons of graphite. It has also lead, zinc, sulphur, salt, and a great variety of useful earths and stones. The value of the mineral output in 1912 was about \$8,759,400. The manufacturing industries are chiefly connected with the mineral products. There are large mills for the production of rails, sheet iron, wire, and smaller iron and steel articles. There are also several extensive machine shops, glassworks, distilleries, breweries, tobacco factories, and paper mills. The principal domestic exports are fruits, timber, cattle, and metal products. The Diet of Styria is composed of 87 members, representing the landed aristocracy, the towns and industrial centres, the rural communities, and chambers of commerce. In the lower house of the Austrian Reichsrat Styria is represented by 30 delegates. In 1911 Styria had 919 public elementary schools, attended by 202,542 children, or about 95 per cent of the school population. Pop., 1900, 1,356,494; 1910, 1,444,157. Over 70 per cent are German and over 29 per cent Slovenian; about 98 per cent are Roman Catholic. The principal towns, with 1910 population, are: Graz (q.v.), the capital, 151,781; Marburg, 27,994; Eggenberg, 12,745; Leoben, 11,025.

**History.** Under Roman control the territory of Styria formed a portion of both Pannonia and Noricum, and was even then famous for its iron and steel. During the period of the great migration of nations the various invaders of the Italian peninsula swept through or settled in this district and at the close its population was essentially Slavic. It was a portion of the empire of Charles the Great, and was later included in the Carinthian mark erected against the Hungarians. Soon after the middle of the eleventh century the Margrave Ottokar styled himself Margrave of Steier, whence the region came to be known as Steiermark (Styria). In 1192 the region that is now the Duchy of Styria became a portion of the possessions of the dukes of Austria, and after belonging for a time to Ottokar II of Bohemia, passed in 1276 into the possession of the Hapsburgs. The Reformation was welcomed by the people, but the intolerance of the Austrian rulers drove many of the inhabitants into exile.

Mayer, *Geschichte der Steiermark* (ib., 1898).

**STYRIA, OTTOKAR OF.** See OTTOKAR OF STYRIA.

**STYX** (Lat., from Gk. Στύξ, from στυγεῖν, *stugein*, to hate, loathe). In Greek legend, one of the rivers of the lower world: it was originally, perhaps, the only stream which separated the region of the dead from the living. One-tenth of Oceanus streamed down to form the Styx, the other nine-tenths surrounded the earth. As the goddess of this stream, Styx was the

eldest daughter of Oceanus, and became, by the Titan Pallas, mother of Zelos, Nike, Cratos, and Bia (Emulation, Victory, Might, and Force), with whom she joined Zeus at the beginning of the struggle with the Titans. For this she was made the guardian of the sacred oaths which bound the gods. She was described as living in the far west, in a house with silver pillars, where the water streamed from above. Thence Iris brought the water by which the gods swore, and terrible suffering awaited the divinity who committed perjury. With the development of the conceptions of the lower world, the rivers received various names, and Charon was introduced as the ferryman of souls across the Styx. The name was also given to a waterfall in northeastern Arcadia, near Nonacris. The water descends over a cliff some 600 feet high on the side of Mount Chelmos into a wild and rugged glen, and the surroundings suggested to the Greeks the gloomy entrance to the lower world.

**SUABIA.** See SWABIA.

**SUAHELI**, swā-hē'li. A people of Africa. See SWAHILI.

**SUAKIM**, swā'kim, or **SUAKIN**, swā'kin. A seaport of Egyptian Sudan, on a small island in the Red Sea (Map: Africa, H 3). It is connected with the desert mainland by a railroad bridge. The town consists of two main parts. The government buildings and the residences of the official class in the one section present an imposing appearance in direct contrast to the wretched dwellings of the natives in the other section. Suakim is conspicuous as the embarking place for African pilgrims traveling to Mecca. It has a well-protected harbor and is an important shipping point for the products of the interior. These include ivory, tobacco, and gums. The trade is increasing, but the city suffers from the competition of Port Sudan. The domestic manufactures are lance heads, cutlery, and leather cases. Suakim was founded by the Turks, and was a slave port until the traffic was suppressed. The vicinity of Suakim was a battle ground between the Anglo-Egyptians and Osman Digna in 1884 and 1890. Pop., 1905, 10,500.

**SUANITIANS**, swā-nish'anz, or **SWANS**. One of the Georgian peoples of the Caucasus, dwelling in the Transcaucasian Province of Kutais between the Imeritians and the Mingrelians (qq.v.). See also GEORGIANS.

**SUARDI**, swär'dē, BARTOLOMEO, called BRAMANTINO (c.1460-1529). An Italian painter and architect of the Lombard school. He studied in Milan and was early influenced by Foppa. Later he became the assistant and imitator of Bramante, whence his surname. He distinguished himself as an engineer at the defense of Milan in 1523 and was appointed court architect to Duke Francis (II) Sforza in 1525. His types have grandeur and sensitiveness, his architectural backgrounds are very fine, and his color scheme is original. Among his best-known paintings are the frescoes of "St. Martin" and "Madonna and Angels" (Brera, Milan); "Adoration of the Magi" (Layard Collection, Venice); "Flight into Egypt" (Santa Maria del Sasso, Locarno); "Ecce Homo" (Certosa of Pavia) and "Calvary" (New York Historical Society).

**SUÁREZ**, swā'râth, FRANCISCO (1548-1617). A Spanish theologian and scholastic philosopher. He was born at Granada, entered the Jesuit

Order in 1564, and came under the direction of the great ascetic Rodriguez during his novitiate at Medina del Campo. The general of the society, Aguaviva, called him to teach in Rome (1580-85). Returning to Spain for reasons of health, he taught at Alcalá, Salamanca, and Coimbra. Besides his thorough knowledge of the schoolmen, and especially of Thomas Aquinas, whom he usually follows, he displays remarkable familiarity with the writings of the first Christian centuries. His complete works were reprinted in 28 volumes (Paris, 1856-61). Consult Werner, *Franz Suarez und die Scholastik der letzten Jahrhunderte* (Regensburg, 1861).

**SUÁREZ MUJICA**, swä'räs mōō-hē'kà, EDUARDO (1850- ). A Chilean statesman and diplomat, born in Santiago and educated at the university there. As acting Secretary of Foreign Affairs (1882-88), Governor of Atacama (1901-03), member of Congress (1903-09), and Minister of Justice and Public Instruction (1908) he proved his ability as a public official. He began his diplomatic career in 1909 as Minister to Mexico and Cuba, and two years later was appointed Minister (from 1914, Ambassador) to the United States. He took an active part in Pan-American affairs, being a member of the Niagara Falls Conference to discuss the relations of the United States and Mexico (1914) and of the Pan-American Conference on Mexico (1915), which determined on the recognition of Carranza.

**SUAVIS**. See LOMBARD, LAMBERT.

**SUBALTERNATE PROPOSITIONS**. See OPPOSITION.

**SUBANDHU**, sōō-bānd'hōō. A Sanskrit novelist, who lived probably in the latter part of the sixth century A.D. Apart from a few verses he is known as the author of the *Vāsavadattā*, a highly artificial romance dealing with the love of Prince Kāndarpakētu for the Princess Vāsavadattā. The action of the novel is very slight, and the style abounds in long compounds, conceits, and assonances. The novel is important in Sanskrit literary history as being the first of the romantic school, and thus being the acknowledged model for the *Kādambarī* and the *Harsacarit* of Bana (q.v.). It has been edited by Hall (Calcutta, 1859) and Vidyasagara (ib., 1874), and in Telugu script at Madras (1862); and has been edited and translated into English with an admirable introduction and lexicographical appendix by L. H. Gray (New York, 1913). See NOVEL.

**SUBANUN**, sōō-bā'nūn. A partially Mohammedanized tribe which inhabits the Sibuguey Peninsula of Mindanao. Their garments and dwellings resemble those of the Moro. Each settlement has a headman, with a home large enough to accommodate several families. Their agriculture is still primitive, with a scant yield. The deficiency is supplied by forest products and game. Consult E. B. Christy, *Subanuns of Sindangan Bay* (Manila, 1909). See PHILIPPINE ISLANDS.

**SUBBITUMINOUS COAL**. See COAL.

**SUBCONSCIOUSNESS**. A term applied, somewhat indefinitely, to degrees of consciousness which are lower than the highest degrees of attention, or even lower than the conscious levels accessible to introspection. Its principal uses are: (1) as an arbitrary term, referring to a recognized form of psychoneural disease (e.g., hysteria, q.v.) and not implying a theory

or description of that disease (Janet). (2) As the obscure or non-focal content of consciousness, which is observable but unobserved (Stout). Observation in this sense is usually equivalent to cognition, and the obscurity of the subconscious processes is a matter of awareness rather than of attentive clearness. (See ATTENTION; MEANING; NOETIC CONSCIOUSNESS.) (3) As dissociated passive ideas, which exist alone, partially or entirely out of associative relations to the ideas of consciousness proper. (4) As dissociated active ideas, which exist apart from the normal or personal consciousness, but which are actively functioning either to become conscious or to produce some effect upon the behavior or the physiological state of the individual (Sidis, Freud). (5) As a dissociated personality, psychologically complex and internally organized, which functions and develops independently (Prince). Such a dissociated personality or coconsciousness may be thought of as alternating with the principal or personal consciousness, or as persisting simultaneously with it. In the latter case, there may be an alternation of the dominance of the two consciousnesses, or both consciousnesses may appear, by the inconsistent behavior of the individual, to be in effective function at the same time. (See DOUBLE CONSCIOUSNESS; HYSTERIA; TRANCE.) (6) As the sum of all material reproducible in consciousness (Sidis). The theory here is that an idea, in order to be reproduced in memory, must in the meantime be conserved as idea; and since it is obviously not conscious, it must be subconscious. (7) As the physiological (nervous) phenomena which are correlated with the idea and account for its reproduction (Münsterberg, Ribot, Prince). On this view the idea, which is psychological, is conserved, not in kind, but by the nervous system. (8) As a psychical concept, which explains the apparent conservation of ideas without implying that the subconscious is phenomenally actual (Hart). (9) As a teleological principle, which insures the production, with lowered oversight, of (mental) sequences that present a more or less striking infusion of cohering purpose (Jastrow). (10) As the absolute, a philosophical conception.

It should be observed that, on most of these views, the subconscious baffles introspection, is phenomenally unobserved, and is inferred in order to explain certain psychological phenomena. If, however, we cannot observe the subconscious as actual, we have no reason to assume that it is conscious at all, and the term becomes a misnomer. In this case, then, as in others, we must look to the nervous system for the explanation of psychical phenomena and of facts of behavior; and our point of view will thus coincide approximately with the seventh above.

**SUBCONTRARY PROPOSITIONS.** See OPPOSITION.

**SUB/DEA/CON.** A member of a major order in the Roman church, who is bound to celibacy. The subdiaconate apparently originated later than the episcopate, presbyterate, and diaconate, and probably developed from the last named as deacons rose in importance. It is first mentioned in a letter of Pope Cornelius (255). The function of the office is to assist the deacon, in modern times especially in the celebration of the Eucharist. In the Roman Catholic church the subdeacon of the mass is not necessarily or usually a priest. Consult Reuter, *Das Subdiaconat* (Augsburg, 1890), and see DEACON; ORDERS, HOLY.

**SUB/DOMINANT.** The interval one-fifth below the tonic, and the fourth degree of the scale.

**SUBLIACO**, sŭb'è-ì'kò (Lat. *Sublaqueum*). A city in the Province of Rome, Italy, in the Sabine Mountains, 47 miles by rail east of Rome, on the Teverone (ancient Anio) (Map: Italy, D 4). Here are to be seen walls and terraces of one of Nero's villas, and the famous monasteries of Santa Scolastica (founded in 507) and of San Benedetto, the cradle of the Benedictine order of monks. Here in 1465 the Germans Arnold Pannartz and Conrad Schweinheim published the first book printed in Italy, and copies of their editions of Lactantius, Cicero, and Augustine are still in the monastery library, which has lost, however, most of its precious manuscripts. San Benedetto contains thirteenth-century frescoes and paintings. Pop. (commune), 1901, 8005; 1911, 8215.

**SUBIN/FEUDA/TION** (from Lat. *sub*, under + *ML. infeudatio*, infeudation, from *infeudare*, *infeodare*, to confer in fee). The act by which a feudal lord granted a portion of his lands to a tenant upon condition that the latter hold of the former subject to the incidents of feudal tenure. This was accompanied with the feudal ceremonies usual in those times. It was by this means that the feudal manors of England were created. As this practice tended to evade the feudal rules against alienation it was forbidden by the famous statute of Quia Emp-tores. See FEUDALISM; MANOR; REAL PROPERTY; TENURE.

**SUBJECT** (OF. *subject*, *subject*, Fr. *sujet*, from Lat. *subjectus*, subject, inferior, from *sub*, under + *jacere*, to throw). A person who by reason of birth in a country or naturalization under its laws owes allegiance to its sovereign power. The term is almost exclusively employed to denote such a person under a monarchical form of government; whereas, the word citizen is applied to a member of a republic. The rights, privileges, and duties of subjects, of course, depend upon the form of government, and they may differ in political rank and station; thus a duke or an earl is as much a subject of the crown of England as a peasant, although the former is entitled to certain dignities and honors which the latter does not possess. Until recent times (1870 in England); European governments almost universally refused to recognize the right of a subject to change his allegiance, but they now generally

concede this. The policy of the United States in permitting aliens to become citizens by naturalization has probably influenced such nations in changing their arbitrary and despotic attitude on this question, as, of course, it would lead to international difficulties if a naturalized citizen of the United States were to be treated as a subject of the nation whose sovereignty he had renounced in order to become a citizen of the Republic. Consult A. P. Morse, *Treatise on Citizenship* (Boston, 1881). See ALIEN; ALLEGIANCE; CITIZEN; NATURALIZATION, and the references there given.

**SUBKINGDOMS, ANIMAL.** See CLASSIFICATION OF ANIMALS.

**SUBLAPSA/RIAN.** See INFRALAPSARIAN.

**SUBLICIAN** (sŭb-lish'an) **BRIDGE** (Lat. *Pons Sublicius*). The most ancient of the bridges over the Tiber at Rome, ascribed by tradition to Ancus Marcius. The Sublician remained the only bridge at Rome until the second century B.C. It was twice carried away and restored and its piers remained through the Middle Ages. The last remnants were destroyed in 1877. Consult S. B. Platner, *The Topography and Monuments of Ancient Rome* (2d ed., Boston, 1911).

**SUBLIMATION** (Lat. *sublimatio*, an uplifting, from *sublimare*, to uplift, from *sublimis*, lofty, from *sub*, under + *limen*, threshold). A term applied to the distillation of those volatile solids that, when heated, pass into the gaseous state without melting. Such substances, including iodine, arsenic (i.e., arsenious acid), the chlorides of iron and aluminium, certain organic compounds, etc., may be readily freed by sublimation from nonvolatile impurities. It may be observed that all solids, theoretically without exception, give off more or less vapor, i.e., sublime, even at extremely low temperatures, and of course the evaporation (q.v.) is accompanied by absorption of heat. Ordinarily the rate of evaporation of solids is too small to prevent the temperature from rising to the melting point on the application of heat. But in the case of solids that are very volatile and have a somewhat high melting point the heat applied may be largely used up by the rapid evaporation, and so the temperature cannot rise high enough for the substances to melt. Of course, by placing such substances in a closed vessel and thus preventing free evaporation, they may be readily caused to melt.

**SUBLIME PORTE.** See PORTE.

**SUBLIM/INAL CONSCIOUSNESS** (from Lat. *sub*, under + *limen*, threshold). Literally a degree of consciousness below a certain theoretical limit of intensity or clearness. See SUBCONSCIOUSNESS; UNCONSCIOUS, THE.

**SUBLITTORAL FACIES.** See PALEONTOLOGY.

**SUBMARINE BOAT.** See TORPEDO BOAT, SUBMARINE.

**SUBMARINE GUN** (from Lat. *sub*, under + *marinus*, pertaining to the sea, from *mare*, sea). A gun which discharges its projectile beneath the surface of the water. In 1797 a Frenchman, M. Reveroni Saint-Cyr, proposed to arm a catamaran with a submarine gun, but no attempt is known. Robert Fulton and other Americans attempted the construction of effective submarine guns, but without practical results. Ericsson was the most successful, and his experiments extended over several years.

The difficulty of securing accuracy, the shortness of range, and the improvement of the automobile torpedo tended to discredit the gun. Torpedoes are now discharged from submerged tubes, but these are not properly guns, as the projectile force is merely sufficient to clear the torpedoes from the ship's side. In the Davis torpedo a gun is fitted which fires its projectile through the enemy's bottom upon contact or being stopped by a torpedo net. See **TORPEDO**.

**SUBMARINE MINES.** See **MINE**, **SUBMARINE**; **TORPEDO**.

**SUBMARINE TELEGRAPH.** See **TELEGRAPHY**, **SUBMARINE**.

**SUBMARINE TORPEDO BOAT.** See **TORPEDO BOAT**, **SUBMARINE**.

**SUBMAXILLARY GANGLION** (from Lat. *sub*, under + *maxilla*, jaw, jawbone). One of the four sympathetic ganglia lying in the cephalic region, sometimes called cranial ganglia. The latter term is rather misleading, as none of the ganglia are within the cranial cavity. The submaxillary ganglion is situated above the deep portion of the submaxillary gland. (See **SALIVARY GLAND**.) It is connected by filaments with the lower border of the gustatory nerve (nerve of taste, supplying the tongue). It also receives motor filaments from the chorda tympani nerve, a branch of the facial. It is small, rounded, and of a reddish-gray color; its branches of distribution, five or six in number, arise from the lower part of the ganglion, and supply the mucous membrane of the mouth and Wharton's duct, some being lost in the submaxillary gland. The other three ganglia are Meckel's, the ophthalmic, and the otic (qq.v.).

**SUBMERSIBLE TORPEDO BOAT.** See **TORPEDO BOAT**, **SUBMARINE**.

**SUBORDINARY.** A class of charges in heraldry (q.v.).

**SUBORNATION OF PERJURY.** The offense of procuring a person to commit perjury. The crime will not be committed unless both the person inducing and the person testifying have knowledge that the testimony is false. Although only a misdemeanor at common law, in most jurisdictions to-day it is punished with the same severity as perjury. See **PERJURY**.

**SUBPŒNA** (Lat. *sub pœna*, under penalty, the initial words of the writ in its original form). A mandatory writ or process issued by a court, a quasi-judicial body, or an official having judicial powers, commanding a person or persons named therein to appear at a certain time and place and testify or furnish documentary evidence in an action or judicial proceeding. Originally a subpœna was used only to compel attendance of witnesses in court, but by statute in most States many officials and bodies having judicial powers, such as boards of commissioners, coroners, legislative committees, etc., are authorized to compel the attendance of witnesses by this process.

A subpœna intended only to compel the attendance of a witness for the purpose of giving testimony is known as a subpœna *ad testificandum*. Where it is necessary to put in evidence documents which are in the possession of a witness, he may be compelled to appear and produce them by a subpœna *duces tecum*. This form of subpœna is substantially like the one above mentioned, except that it specifically enumerates as far as possible the books, papers, and documents desired. In some code States a

"notice to produce" served by one attorney in an action on his opponent serves the same purpose. It is no excuse that the papers are of a private nature; they must be produced nevertheless, and the court will then upon inspection rule whether they are privileged or not. Where the documents are incriminatory of the person directed to produce them, however, they need not be brought to court.

In most States a subpœna may be served by any person of discretion, who usually must be 18 years of age or upward, and service is made by delivering a copy of the subpœna to the witness personally, at the same time showing him the original, and paying or tendering his legal fees and expenses, which are fixed by statute. Failure to appear in obedience to a subpœna is a contempt of court. It is usual for the party who caused the service of the subpœna to apply to the court for an order directing the witness to show cause why he should not be punished for contempt. Such a witness is also liable in a civil action for all damages which may have been caused by his nonappearance to the party calling him. A witness may be excused, in the discretion of the court, upon reasonable cause, as illness, death in family, etc. Prior to 1852 a defendant was summoned to answer an action in a court of chancery in England by a subpœna *ad respondendum*. This practice has been superseded there by service of a copy of the bill instead, but still obtains in some jurisdictions in the United States. Such a subpœna corresponds more nearly in its purposes to a summons than a subpœna as above described. Consult authorities referred to under **PROCEDURE**. See **EVIDENCE**; **SUMMONS**; **WITNESS**.

**SUBROGATION** (ML. *subrogatio*, from Lat. *subrogare*, *surrogare*, to substitute, from *sub*, under + *rogare*, to ask). The treatment of one who has paid the debt or fulfilled the obligation of another, which as between himself and that other should have been paid by the latter, as though he were the assignee of the creditor's claim. The payer is then said to be subrogated to all the rights and remedies of the creditor against the primary debtor. The doctrine upon which this subrogation is based was originally applied by courts of equity, but is now generally applied by courts of law to all cases where one pays a debt on which he is secondarily liable, although the debt may be legally discharged by the payment. Equity, for the purpose of working out justice between the parties by repaying the advances made, deals with the case as though the debt were still in existence, and gives to the person paying the debt precisely the same rights and remedies as belonged to the original creditor, but in no case does one by subrogation acquire any higher or different rights. It will thus be seen that the analogy between subrogation and assignment is complete, one who is entitled to be subrogated to a claim or demand being treated as though he were an assignee of the claim or demand. The only difference between them is the source and not the character of the right, the right to subrogation arising by operation of law and the right of an assignee arising by voluntary act of the parties.

Since the principle is of equitable origin the maxim that one asking the aid of equity must come into court "with clean hands" applies; and subrogation will take place only where the per-

son satisfying the obligation was under a legal or equitable obligation to do so. Thus a person may not voluntarily pay the debt of another and still be subrogated to his rights against third parties.

Some of the more important cases in which the doctrine is applied are: (1) Where a junior mortgagor pays off a mortgage prior to his own, when equity will compel an actual assignment of the mortgage by the prior mortgagee. (2) When one pays a debt to the payment of which he is entitled to contribution by others, or for which others are primarily liable and he only secondarily, as in the case of a surety. In these cases, since the sole relief sought is payment of money, courts of law apply the doctrine, and give a complete remedy. (See CONTRIBUTION; QUASI CONTRACT; SURETYSHIP.) (3) In some jurisdictions, particularly in England, when one paying money to a corporation under an ultra vires contract cannot recover in quasi contract, although it is used by a corporation in paying its corporate indebtedness, in which case the person so advancing money is subrogated to the rights of the original creditor. (4) In the case of insurance contracts and contracts of indemnity generally whenever the insurer or indemnitor pays the indemnity due under his contract, he is entitled to be subrogated to the rights of the person indemnified against third parties which may in any manner reduce the loss or obligation indemnified against. See CHANCERY; EQUITY; INDEMNITY; INSURANCE.

**SUBSCRIPTION** (Lat. *subscriptio*, from *subscribere*, to subscribe, write under, from *sub*, under + *scribere*, to write). A popular rather than a technical term in law signifying a written contract by which a person agrees to contribute a sum of money for a specified purpose. The subscription may be made either as a gift, or it may be made as an offer to pay the money subscribed in exchange for property to be delivered to the subscriber. Whenever the person or corporation in whose favor the subscriptions are made has performed work or incurred expense or liability, relying upon such subscriptions, the courts have generally held that such expense or liability is a sufficient consideration for the subscription to make it a legally enforceable contract, entitling such persons or corporation to sue upon it. It has also been held that when there are several subscribers and each subscriber has fair notice that others are expected to subscribe to the same object or purpose, the promise of each subscriber is consideration for the promises of all the others. The soundness of such a doctrine may well be doubted and the authorities upon this point are in conflict. A subscription for stock of an existing corporation is generally deemed to be a mere offer which may be withdrawn at any time before acceptance, but which may be accepted at any time before withdrawal of the subscription by an allotment of the stock to the subscriber. Upon such acceptance the subscription becomes a valid contract which may be enforced by the corporation. A subscription for stock in a corporation to be formed will not generally ripen into a contract upon the incorporation of the company and the allotment of the stock, since there was no promise in existence at the time of the making of the offer of subscription. Where several of such subscribers mutually agree to take stock, however, the agreement of each will bind him contractually towards all the others.

See CONSIDERATION; CONTRACT; CORPORATION; STOCKHOLDERS.

**SUBSIDENCE.** See ELEVATION AND SUBSIDENCE.

**SUBSIDIES** (Lat. *subsidiū*, relief, aid, auxiliary force, from *subsistere*, to sit down, remain, subside, from *sub*, under + *sedere*, to sit). A term in English history having reference to special tax assessments upon persons and not directly upon real property; in general European politics it has reference to grants of money to an ally to aid in the prosecution of war; while as a current economic term it applies to grants of money made by the state in aid of individual enterprises. See BOUNTY; MERCHANT MARINE; SHIPPING SUBSIDIES.

**SUBSOILING.** See PLOW, PLOWING.

**SUBSTANCE** (OF. *substance*, *substantie*, Fr. *substance*, from Lat. *substantia*, being, essence). A term frequently used in logic and metaphysics with varying meaning. Substance is correlative with quality or attribute. Every substance must have attributes, and every attribute must be the attribute of some substance. The substance gold has the attributes weight, color, etc. Now it is not difficult to identify attributes and to give a definite meaning to our conception of them. But what is the substance to which they belong? What is left of gold, e.g., when its color, characteristic hardness, specific gravity, chemical affinities, etc., have been all catalogued among its attributes or qualities? Now, however difficult it may prove to answer this question when once it is raised, popular thought and popular philosophy assume that everything whatsoever possesses, besides its attributes, a substratum; that they rest upon or inhere in something that holds the attributes together, without being itself an attribute. Without being clear in details on the subject it is assumed that the attributes could not hang together so consistently and persistently by themselves. The problem is solved by metaphor. The very terms "substance," "substratum," "inherence" are all metaphorical, but no plain statement is made of what is figuratively alluded to.

This vague view appears at the very dawn of philosophical speculation, having been doubtless an inheritance from prescientific and pre-critical thinkers, and has persisted through all the centuries up to the present. When speculation began in the Western world, an attempt was made to identify the assumed substance with some well-known type of experienced object. Substance appears in the doctrine of the Ionic philosophers (see IONIAN SCHOOL) as air or earth or water, in Heraclitus (q.v.) as fire, but in Parmenides (q.v.) it becomes an abstraction, pure being. In Aristotle we have a more critical view, according to which the individual realities of experience are substances, while species are second substances. The Stoics returned to the idea of a substrate as the bearer of attributes, and this view persisted through the Middle Ages as the only one advocated, except by the Nominalists. (See NOMINALISM.) In modern philosophy Descartes and Spinoza share this substrate theory. Leibnitz moved away from this static conception and regarded substance as a being capable of action or "primitive force," but it was his great opponent Locke who definitely acknowledged that substance, while apparently a necessary inference, is in reality unknowable.

Berkeley went further. Locke had accepted the existence of material as well as spiritual "powers"; Berkeley maintained that "the supposition of external bodies is not necessary for producing our ideas, since it is granted they are produced sometimes, and might possibly be produced always in the same order we see them in at present, without their concurrence." Hence "there is not any other substance than *Spirit*, or that which perceives." About this substance, however, Berkeley could give no consistent account. At one time we are told that thing or being "comprehends under it two kinds entirely distinct and heterogeneous, which have nothing in common but the name, viz., Spirits and Ideas. The former are active, invisible substances—the latter are inert, fleeting, or dependent beings, which subsist not by themselves, but are supported by or exist in minds or spiritual substances." But in another place we are told that "*the soul always thinks*; and in truth whoever shall go about to divide in his thoughts or abstract the existence of a spirit from its *cogitation*, will, I believe, find it no easy task." Hume developed the idea contained in the last quotation and arrived at the result that all substance is an "unintelligible chimæra."

Kant emphasized the "relations" which united perceptions, and found in them the essence of substance. Substance with him is a category of relation which, when schematized, i.e., brought into relation with time and space, becomes "the permanence of the real in time, or the idea of the real as presupposed in the empirical determination of time, and as persisting while all else changes." But this view has a defect. There is too much absoluteness in the conception. It is not necessary that there should be anything which persists through all changes. It is only necessary that there should be some quality which remains *relatively* unchanging, while other qualities change. The relatively permanent quality forms then the nucleus around which the changes gather as variations of a thing. The same thing does not always remain unchanged in the same quality. Now it may be this quality, now that. On this account some philosophers prefer to regard substantiality as shifting from time to time.

But perhaps a more empirical definition of substance can be obtained from the theory of judgment. Going back to Aristotle's conception of substance (*οὐσία*) as that of which predication is made, we find (see JUDGMENT) that predication is always made of a synthesis of attributes. The orange is yellow, grows on a tree, developed from a flower, is going to be eaten by me next minute, etc. The orange is the synthesis of all these quantities or attributes, some of which may be past and some not yet existent. The only object of which all the qualities of an orange are predicable is the totality of the predicable qualities. This totality exists at any one time, not as a whole, but in part. Now the synthesis of all the qualities which appear to common sense as the qualities of a thing is itself in this view regarded as the substance of that thing. Used in this sense substance is no longer what its etymology indicates, viz., a something standing behind phenomena, but it is what the Greek term *οὐσία* means, viz., the being of which attributes are predicable. A realistic modification of this

view is possible according to which substance would be the synthesis of such qualities as have existence outside of experience. See METAPHYSICS: PHILOSOPHY; SCHOLASTICISM.

**SUBSTANTIVE COLORS.** See ADJECTIVE COLORS.

**SUBSTANTIVE LAW** (Lat. *substantivus*, self-existent, substantial, real, from *substantia*, being, essence, material). That branch or division of the whole law which defines and establishes human rights and privileges with reference to property and prescribes rules of conduct to be observed by mankind in the various relations of life. All other law may be classed as adjective or remedial, i.e., as dealing with the methods of enforcement and maintenance of the normal conditions established by the substantive law, and the rectification of such abnormal social conditions as may arise. For convenience the substantive law is subdivided into various branches according to the subject matter to which it relates. For example, we speak of the law of real property, of personal property, the law of domestic relations or persons, etc. It is to be found both in legislative enactments and in the rules and precedents of the common law. See LAW and the authorities there referred to.

**SUBSTITUTION** (Lat. *substitutio*, a putting in the place of another, from *substituere*, to put in the place of another, from *sub*, under + *statuere*, to place, from *stare*, to stand). A mathematical operation by which one expression is replaced by another. The term has, however, come to have a technical meaning in modern mathematics, and this has led to an important branch known as the theory of substitutions. If  $n$  elements,  $a_1, a_2, a_3, \dots, a_n$  are given, and  $a_1, a_2, a_3, \dots, a_n$  and  $a'_1, a'_2, a'_3, \dots, a'_n$  are two arrangements of these elements, the operation of passing from the first of these arrangements to the second is called a substitution of the  $n$  elements. It follows that there are  $n!$  substitutions of  $n$  elements, including the identical substitution, which leaves the order of the letters unchanged. A substitution which in place of the arrangement  $a_1, a_2, a_3, \dots, a_n$  gives  $a'_1, a'_2, a'_3, \dots, a'_n$ , is represented by the symbol

$$\begin{pmatrix} a_1 & a_2 & a_3 & \dots & a_n \\ a'_1 & a'_2 & a'_3 & \dots & a'_n \end{pmatrix}$$

If  $a_1$  is replaced by  $a_2$ ,  $a_2$  by  $a_3$ ,  $\dots$ ,  $a_{n-1}$  by  $a_n$ , and  $a_n$  by  $a_1$ , the substitution is said to be cyclic, and is more conveniently represented by  $(a_1 a_2 a_3 \dots a_n)$ , or even by  $(1\ 2\ 3 \dots n)$ , than by the more elaborate symbol

$$\begin{pmatrix} a_1 & a_2 & \dots & a_{n-1} & a_n \\ a_2 & a_3 & \dots & a_n & a_1 \end{pmatrix}$$

Similarly the substitution  $\begin{pmatrix} abcdef \\ cedafb \end{pmatrix}$

may be written  $(acd)(bef)$ , meaning that while  $a$  changes to  $c$ ,  $c$  to  $d$ , and  $d$  to  $a$ ,  $b$  at the same time changes to  $e$ ,  $e$  to  $f$ , and  $f$  to  $b$ . This symbolism is further extended thus: Consider  $(ab)(ac)$ ; this means that  $a$  changes to  $b$ ,  $b$  to  $a$ , and  $a$  to  $c$ , and  $c$  back to  $a$ , a result which evidently may also be indicated by  $(abc)$ , so that  $(ab)(ac) = (abc)$ . But the same reasoning shows that  $(ac)(ab) = (acb)$ . Hence if  $s_1 = (ab)$  and  $s_2 = (ac)$ ,  $s_1 s_2 = s_2 s_1$ . For convenience,  $s_2 s_1$  is called the *product* of  $s_1$  and  $s_2$  in the order given, from which it appears that the commutative law of multiplication does not hold true in the theory of substitutions. If in the

product  $s_1 s_2 s_3 \dots s_n$  we have  $s_1 = s_2 = \dots s_n$ , the product is called the *power* of each substitution. If a substitution leaves all the elements unchanged in order, it is called an *identical* substitution and is represented by 1. If the product of two substitutions, like

$$\begin{pmatrix} a_1 & a_2 & \dots & a_n \\ a'_1 & a'_2 & \dots & a'_n \end{pmatrix} \text{ and } \begin{pmatrix} a'_1 & a'_2 & \dots & a'_n \\ a_1 & a_2 & \dots & a_n \end{pmatrix}$$

is 1, each is called the *inverse* of the other, and if the first is represented by  $s$ , the second is represented by  $s^{-1}$   $ss^{-1}$  equaling 1.

A collection of substitutions is said to form a *group*, if the product of any two is another of the same collection. This may be illustrated outside the field of substitutions by the three cube roots of unity 1,  $-\frac{1}{2} + \frac{1}{2}\sqrt{-3}$ ,  $-\frac{1}{2} - \frac{1}{2}\sqrt{-3}$ , the product of any two being another of the same collection. The six substitutions  $s_0 = 1$ ,  $s_1 = (xyz)$ ,  $s_2 = (xzy)$ ,  $s_3 = (yzx)$ ,  $s_4 = (zxy)$ ,  $s_5 = (xzy)$  also form a group. The number of substitutions of a group is its *order*, and this is always a factor of  $n!$ . Thus in the group given the order is 6, and this is a factor of  $3!$ . If all substitutions of a group  $H$  are contained in another group  $G$ ,  $H$  is called a *subgroup* of  $G$  and the order of  $H$  is a factor of that of  $G$ . A group whose operations are all permutable with one another is called an *Abelian group*.

Lagrange (1770) was one of the first to undertake a scientific treatment of substitutions in connection with the theory of the quintic equation. He invented a "calcul des combinaisons," the first real step towards the theory of substitutions. Ruffini (1799) was the next to undertake a serious study of the subject, again in the attempt to show the impossibility of solving the quintic. To Galois (q.v.), however, the honor of establishing the theory is usually ascribed. He found that if  $r_1, r_2, r_3, \dots, r$  are the  $n$  roots of an equation, there is always a group of permutations of the  $r$ 's such that (1) every function of the roots invariable by the substitutions of the group is rationally known, and (2), reciprocally, every rationally determinable function of the roots is invariable by the substitutions of the group, a discovery that eventually led to the proof of the insolubility of the quintic. A. L. Cauchy was the first of the well-known French mathematicians to recognize the importance of the theory, and numerous important propositions are due to him.

**SUBSTITUTION, THEORY OF.** See CHEMISTRY (historical section).

**SUBTERRANEAN HOUSES.** See EARTH LODGE.

**SUBTRACTION** (Lat. *subtractio*, a taking away, from *subtrahere*, to take away, from *sub*, under + *trahere*, to draw, drag). The inverse of addition, and one of the fundamental processes of arithmetic and algebra. It is the operation which has for its object, given the sum of two

expressions and one of them, to find the other. The given sum is called the *minuend*, the given addend is called the *subtrahend*, and the addend to be found is called the *difference* or the *remainder*.

**SUBURRA.** A district of ancient Rome in the valley between the Esquiline, Quirinal, and Viminal hills. It bore an evil reputation as the resort of peddlers, footpads, and prostitutes. Consult S. B. Platner, *The Topography and Monuments of Ancient Rome* (2d ed., Boston, 1911).

**SUBVENTION.** See SHIPPING SUBSIDIES.

**SUBWAYS (FOR PIPES AND WIRES).** Underground galleries which contain and render accessible at any point the multitudinous pipes and wires beneath city pavements; or else ducts for inclosing underground wires only, in such a way as to make them accessible at intervals. Subterranean passages for the accommodation of street traffic are either nothing more than streets or footpaths placed in tunnels, which need no description, or they are underground railways, which are described in the articles on URBAN TRANSPORTATION and TUNNEL. In connection with these, pipe and wire subways are often built, and this plan has been adopted for some future New York underground systems.

The chief advantages of subways for pipes and wires are: (1) They increase the life and general serviceability of pavements and prevent the interruption to traffic caused by street excavations to gain access to pipes when simply buried in the ground. (2) They facilitate both the inspection and repair of all classes of underground furniture, and thus lessen the number of troublesome and dangerous leaks from water and gas mains; they also aid in the prevention of electrolysis, or the electrical decomposition of iron and lead conduits through stray electrical currents. (3) Ventilated and relatively dry subways may greatly lengthen the life of pipes and wires through better protection against corrosion than is possible when they are laid directly in the earth.

One of the earliest attempts to avoid the disturbance of pavements was carried out in Liverpool, where a gallery  $2\frac{1}{2}$  feet wide was built under the sidewalk and in it were placed an oval pipe sewer  $27 \times 18$  inches, a 10-inch water main, and a 10-inch gas main. The bottom of the trench was 13 feet below the surface of the sidewalk. Little or no provision for repairs was made. The London subways date from 1861 or 1862, when one was built in a new street from Covent Garden Market to St. Martin's Lane. A few months later a subway was built at Nottingham, England. Subsequently a number of subways were added to the first ones built in London and Nottingham. In London there are among other subways a long one under the Thames Embankment and one beneath the new street called Kingsway, built by the London County Council. Subways have also been built in other British towns. The London subways contain gas, water, electric light, hydraulic-power supply, telephone, and telegraph mains. The placing of wires and a great variety of pipes in the sewers of Paris is one of the notable features of that city.

In the United States the nearest approach to subways like those of Europe is at St. Paul, where a number of miles of sewers have been constructed in the form of tunnels in the soft sand-rock which underlies the city, and water

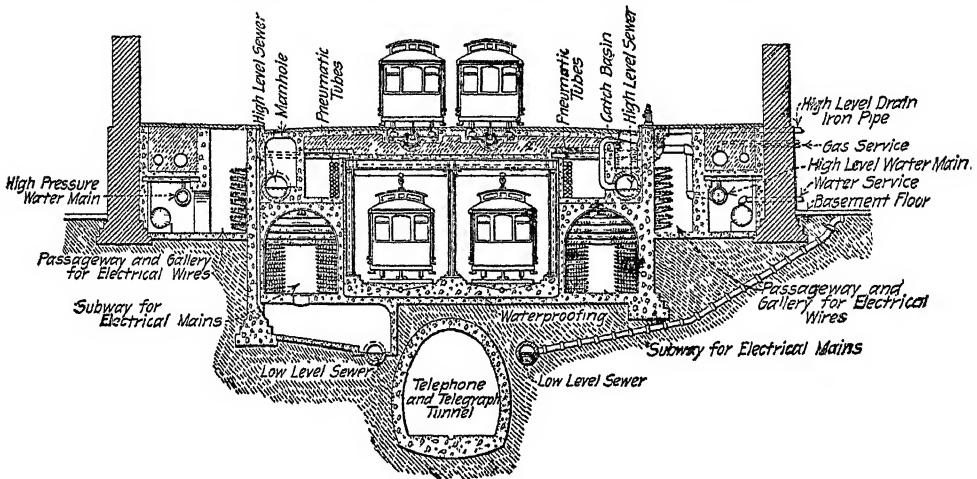

mains have also been placed, separately, in similar tunnels. Branch tunnels connect with the houses in the same general way as branches lead to the buildings along the line of the European subways. Besides the sewers and water mains at St. Paul, some private companies have placed telephone lines in like tunnels. Tunnels for telephone cables have been constructed in Chicago, and are also utilized for conveying freight and express by means of small electric cars. A short length of pipe and wire subway was built in Chicago in 1915.

**Electrical Subways.** In a growing number of the larger cities of the United States electrical wires for light and power, together with the ordinary and the police and fire-alarm telegraph lines, are also placed underground. Electrical subways consist of a single pipe or tube, or a group of such, designed to protect underground wires from injury due to settlement of the earth or the picks and shovels of workmen. At the same time these subways afford access to the

**SUBWAYS.** See TUNNEL; URBAN TRANSPORTATION.

**SUCCESSION** (Lat. *successio*, from *succedere*, to follow, succeed, from *sub*, under + *cedere*, to yield). At civil law (q.v.) succession signifies in general the substitution of one person for another in an existing legal relation. Acquisition of a right previously held by another is termed *active* succession; subjection to a duty previously resting upon another, *passive* succession. When single rights or duties are thus transferred the succession is said to be *singular*. When a person receives all the rights and duties of another that are capable of transfer the succession is said to be *universal*. The most important case of universal succession is inheritance, which at civil law signifies the transfer to one or more heirs or personal representatives of the rights and obligations of a person deceased. Heirs may be designated by a last will or testament (q.v.); in the absence of a valid testament they are designated by general laws.

CROSS SECTION OF CHICAGO STREET, SHOWING PROPOSED ARRANGEMENT OF SUBWAYS.

wires through manholes placed at intervals, for repairs, connections, or the drawing in of new wires. The most common materials used for the conduits or ducts are wrought iron, earthenware, and wood, but sometimes cast iron, and again ordinary or more rarely bituminous cement concrete is used. In place of tubes troughs of cast iron, earthenware, or wood, covered with the same material, are sometimes employed. Wrought-iron pipes similar to gas pipes are commonly embedded in concrete, and they may be laid in trenches lined with cement or wood. The various classes of electrical wires and cables are generally insulated before being placed in subways. (See ELECTRIC LIGHTING; ELECTRIC RAILWAYS; TELEGRAPH; TELEPHONE; ETC.) The wires and cables are drawn into the closed electrical subways through manholes at intervals of 200 to 300 feet by means of ropes or rods. Aside from cities subways or underground tubes are maintained in railway terminals and for certain long-distance telephone cables and telegraph conductors along certain railway lines.

**Bibliography.** Consult Mason, "Street Subways for Large Towns," and discussion thereon, in *Transactions of the Society of Engineers* (London, 1895), and articles in *Engineering News* (New York), for descriptions of numerous subways for pipes and wires.

In the latter case civilians speak of inheritance or succession *ab intestato* (q.v.). Inheritance may also be determined, in part, by laws which give certain persons rights of succession of which they cannot be deprived by a testator except on legally defined grounds. For such limitations upon the power of testation at civil law, see TESTAMENT. Blackstone describes succession at common law as the method by which one set of persons constituting a corporation aggregate acquired the property of the corporation by succeeding another set of persons. See DEATH DUTIES.

**SUCCESSION AB INTESTATO** (Lat., from one intestate). 1. Roman Law. In early Roman law, as in early law in general, succession was governed by the organization of the family. According to the Twelve Tables the inheritance vested (1) in the *sui*, i.e., the members of the decedent's family, who were under his household authority. (See PATRIA POTESTAS.) The sons and the unmarried daughters and the widow who had been in *manu* (see MARRIAGE) had equal shares. Children of a predeceased son received their father's share. Failing *sui*, the inheritance passed (2) to the nearest agnate (i.e., the nearest collateral relative in the male line). If there was no agnate the inheritance went (3) to the *gens* or clan. Under this system kinship gave

no right except in so far as it coincided with the family organization. Emancipated sons and daughters, married daughters and their descendants, and all cognates (relatives in the female line) were excluded from succession. On the other hand, adopted children and the wife *in manu* had the same rights as the other *sui*. In the subsequent development of the law there was a steady movement towards fuller recognition of kinship. This movement began with the prætorian reforms at the close of the Republican period. Emancipated sons and daughters and married daughters were admitted to inherit with the *sui*, on condition of "collating" (i.e., putting into hotchpot) their separate property. Failing agnatic relatives, cognates were admitted; and failing cognates, the husband and wife who had established a free or "consistent" marriage succeeded one to the other's estate. Later Imperial legislation placed cognates and agnates on the same footing, as far as the direct line was concerned (ascendants and descendants). Justinian in his 118th Novel abolished all preference of agnates. Under Justinian's rules the inheritance went (1) to descendants; (2) to ascendants, brothers and sisters of the full blood and their children; (3) to brothers and sisters of the half blood and their children; (4) to the nearest collateral relative; (5) to the surviving spouse; and (6) to the fiscus. Illegitimate children had no rights of succession except from the mother.

**II. Mediæval European Law.** The early German law of inheritance, with the Roman, was based on the family, but it gave no such preference to kinship in the male line, except as regarded succession to real property. As regarded such property, however, a preference not only of the male line over the female, but of male heirs over female, is visible in the earliest written laws; and this preference was emphasized and made general in mediæval Europe by the development of the feudal system. In German law there appeared also a distinction between sword goods and spindle goods, i.e., between things used by men and things used by women, and a tendency to prefer male heirs as regarded sword goods and female as regarded spindle goods. Another German idea was that, when the nearest heirs were of the half blood, property that had come to the decedent from the father's side should go to the paternal relatives, while property that had come from the mother's side should go to the maternal relatives ("paterna paternis, materna maternis"; in Spanish law, "truncalidad"). Sporadically manifested, moreover, was a disinclination to allow property to ascend, with resultant rules preferring brothers and sisters and their descendants to parents.

As between collaterals rights of succession at German law did not depend wholly on nearness of kinship. Descendants of a nearer common ancestor were regularly preferred to descendants of a more remote common ancestor. Inheritance vested (1) in descendants of the decedent; (2) in descendants of his parents; (3) in descendants of his grandparents; (4) in descendants of his great-grandparents, and so on. Within each such group the nearest of kin took the inheritance. This is described by modern writers as the "lineal-gradual" or "parentela" system. Coupled with a preference of the male line and of males within that line it became the (original) feudal law of succession, and (with

preference of the eldest male added) it determined the English law of inheritance of real property.

**III. Modern Civil Codes.** In modern European legislation the Roman principle of universal succession has generally reasserted itself: the same rules generally govern inheritance of realty and of personalty. In all the codes the inheritance vests primarily in descendants. Failing these different rules prevail. At French law the inheritance passes, in second instances, to parents, brothers, and sisters and the children of brothers and sisters, all of whom take precedence of grandparents. The Spanish code prefers all ascendants, and the German code prefers parents, to brothers and sisters. In the absence of descendants, ascendants, and of brothers and sisters and their descendants, the French, Italian, and Spanish codes confer the inheritance upon the nearest collateral; but the French code provides that if there be collaterals both on the paternal and the maternal side the inheritance shall be divided. The Austrian and the German codes follow the parentela system.

The surviving spouse is better treated than at Roman law. Under the Code Napoléon, indeed, the surviving spouse had no right except by antenuptial contract or, in the absence of such contract, by operation of the general law of matrimonial property; but by the law of March 9, 1891, he or she has a life interest in a portion of the property, which is at most one-fourth if there are children, but rises to one-half if there are no children. There are similar provisions in the Italian and Spanish codes; but at Spanish law if the decedent has neither descendants, ascendants, nor brothers or sisters or nephews, the surviving spouse takes the whole estate absolutely; and at Italian law, if there are no legitimate children, the surviving spouse takes from one-fourth to one-third absolutely as against parents and illegitimate children, two-thirds as against collaterals, and the whole estate if there is no collateral within the sixth degree (e.g., a second cousin). The German law is even more liberal: the surviving spouse takes one-fourth absolutely as against children; one-half to three-fourths as against parents, brothers and sisters, and grandparents; and the whole as against the decedent's other relatives.

As to illegitimate children different rules prevail. The French, Italian, and Spanish codes give no rights of inheritance to such children unless they have been recognized. Such a recognized child inherits in concurrence with legitimate children, taking, however, only half the share of a legitimate child. When there are no legitimate children the rights of recognized illegitimate children are greater. By the French law of March 25, 1816, they take the whole estate as against all collaterals, except brothers and sisters and their children. In the German code the illegitimate child, although recognized, has no right of succession in the estate of his father or in those of his father's relatives; but in the mother's estate and in those of her relatives such a child has the same rights as if born in wedlock. For a treatment of subjects in English and American law, see DESCENT; DISTRIBUTION; HEIR; INHERITANCE.

**SUCCESSION DUTY.** See DEATH DUTY.

**SUCCESSION WARS.** The name given to wars arising out of conflicting claims of succession to the throne. Among such wars that have been waged in Europe the following deserve

special notice: (1) The War of the Spanish Succession, 1701-14; (2) that of the Polish Succession, 1733-35; (3) that of the Austrian Succession, 1740-48; and (4) that of the Bavarian Succession, 1778-79.

**War of the Spanish Succession.** This war arose on the death without male heirs of Charles II (q.v.), King of Spain, of the house of Hapsburg, Nov. 1, 1700. The nearest natural heir to the throne was of the royal Bourbon line of France, Charles's elder sister having married Louis XIV; but, to prevent any possible union of the two crowns, a solemn renunciation had been exacted both from Louis and his Queen, for themselves and their heirs. Failing the Bourbons, the next heirs were the descendants of the younger sister of Charles, who had married the German Emperor Leopold I, ruler of Austria, from whom no renunciation had been exacted; and the only issue being a daughter, who had married the Elector of Bavaria, and borne a son, Joseph Ferdinand, this prince was regarded both by Charles II and the Spanish people as rightful heir. As he died in 1699, the question of succession was reopened. Louis XIV claimed the throne for himself, as the son of Philip IV's eldest sister, being, however, again legally barred here by another solemn renunciation. The Emperor Leopold maintained that the Bourbons had by these two renunciations lost all rights of succession, and he claimed the throne as the son of Philip IV's younger sister. (See HAPSBURG, *Family Table*.) Leopold handed his claim to his second son, the Archduke Charles. The Austrian party at first preponderated in Spain; but Louis undermined Austrian influence, and his grandson, Philip of Anjou, was declared the heir (Oct. 2, 1700). On the death of King Charles, Philip appeared in Spain and was recognized as monarch. The Emperor Leopold at once took up arms and sent an army into Italy under Prince Eugene, who defeated the French general Villeroi at Chiari on Sept. 1, 1701. William III, regarding the union of France and Spain under the Bourbons as a menace to the naval interests of England and Holland, and stirred up by the action of Louis XIV in recognizing the Pretender, James Edward Stuart, determined to revive the Grand Alliance against France, and entered into a coalition with Austria and her allies in the German Empire, including Prussia. Savoy, Bavaria, and other German States joined the Bourbons. William's policy was continued by Anne, who succeeded to the English throne in March, 1702, and immediately declared war.

In 1702 Churchill (the future Marlborough), with an English-Dutch-German army, made a victorious advance against the French in the Spanish Netherlands; while a German army under the Margrave of Baden crossed the Rhine and encountered Villars, who proved too powerful for them. In Italy, Prince Eugene, after taking Villeroi prisoner at Cremona (January, 1702), was checked by Vendôme. In 1703 Marlborough gained fresh successes and the Duke of Savoy joined the Grand Alliance. The first great blow was struck on Aug. 13, 1704, when the combined Austrian-German-British army under Marlborough and Prince Eugene defeated the French and Bavarians under Tallard at Blenheim (q.v.). A few days before Gibraltar had fallen to the English. The campaigns of Marlborough in Germany and of Eugene in Italy in 1705, while successful, were not

very important. In 1706 Marlborough suddenly attacked the French and Bavarians under Villeroi at Ramillies (q.v.), and routed them. The victory of Eugene over Marsin at Turin in the same year shattered the French power in Italy.

Meanwhile in 1704 the Archduke Charles landed at Lisbon with a British and Dutch army and invaded Spain. Next year the Earl of Peterborough and Sir Clowdisley Shovell landed with a small body of troops in Catalonia. Attacked from both east and west, the Bourbon forces were beaten and driven across the Pyrenees. After Peterborough's departure the Bourbon commander, the Duke of Berwick (q.v.), made head against his antagonists, and by his victory at Almansa (April 25, 1707) recovered the whole of Spain except Catalonia. In the Netherlands Marlborough and Prince Eugene defeated Vendôme's army at Oudenarde (1708), and the capture of Lille, Ghent, and Bruges followed. France, nearly exhausted, made overtures of peace, but the demands of the allies were so exorbitant that Louis XIV preferred to continue the war. The French under Villars suffered another great defeat in September, 1709, at the hands of Marlborough and Prince Eugene at Malplaquet (q.v.). The death of Emperor Joseph I, the successor of Leopold I (April 17, 1711), and accession in the Austrian dominions and in the German Empire of his brother, Charles VI, rescued France, for England now became lukewarm in support of a cause the success of which would result in the union of Austria and Spain; and the English Tories coming into power, England concluded an armistice with France in 1712. Prince Eugene still carried on the war, aided by Holland, but was compelled to give way; and in the spring of 1713 Holland, Prussia, and Savoy joined England as parties to the Peace of Utrecht (q.v.). The Emperor Charles VI was forced to conclude a treaty of peace at Rastatt, March 7, 1714, and later the formal treaty of Baden (in Aargau), Sept. 7, 1714, ended the struggle, leaving Philip on the Spanish throne, but with the provision that the crowns of France and Spain should never be united in the same person; while Austria obtained the Spanish Netherlands, the former Duchy of Milan, Naples, and Sardinia. Sicily was awarded to Savoy, but exchanged for Sardinia. Gibraltar and Minorca were ceded to England, which acquired Arcadia from France. The conflict between English and French in America as part of the War of the Spanish Succession is known as Queen Anne's War.

Parnell, *The War of Succession in Spain* (London, 1888); J. W. Fortescue, *History of the British Army* (ib., 1899); *Cambridge Modern History*, vol. v (New York, 1908), containing a bibliography; K. von Noorden, *Europäische Geschichte im 18ten Jahrhundert: Der spanische Erbfolgekrieg* (3 vols., Düsseldorf, 1870-83), the most comprehensive work on the subject. See LOUIS XIV.

**War of the Polish Succession.** In 1733 Augustus II of Poland and Saxony died and Stanislas Leszczynski (q.v.), whose daughter had married Louis XV of France, was elected King by the Diet through French influence.

Some of the nobles were determined that the crown should pass to Augustus (Frederick Augustus II of Saxony), son of the late King. Russia and Austria supported Augustus and a Russian army placed him on the throne. Stanislas withdrew to the fortress of Danzig, where he held out until June, 1734. France, in retaliation for Austria's support of Augustus III, declared war on the Emperor. The French forces invaded Lorraine and fought successfully on the Rhine (1733-34). Charles Emmanuel III of Sardinia took up arms against Austria, and in 1734 Don Carlos, son of Philip V of Spain, seized the opportunity to undertake the conquest of the Two Sicilies, wrested from Spain in the War of the Spanish Succession. The Austrians were overthrown at Bitonto on May 25, 1734, and in 1735 Don Carlos was crowned King of the Two Sicilies. By the preliminaries of Vienna (Oct. 3, 1735), Austria relinquished the possession of these regions. Augustus III was recognized as King of Poland, though Stanislas retained the royal title and was given for life the duchies of Lorraine and Bar, which were afterward to revert to France. Francis Stephen, dispossessed Duke of Lorraine, received the Grand Duchy of Tuscany. France lent its guarantee to the Pragmatic Sanction (q.v.) and Parma and Piacenza were given the Emperor by Don Carlos. The definitive Peace of Vienna was not signed till 1738. Consult *Cambridge Modern History*, vol. vi (New York, 1909).

**The War of the Austrian Succession.** This struggle arose after the death of the Emperor Charles VI (q.v.), in 1740. In accordance with the Pragmatic Sanction (q.v.) Charles VI's daughter and heiress, Maria Theresa, had received assurances of support from most of the European powers, but hardly had she ascended the Austrian throne when she found her dominion contested on every side. Frederick the Great of Prussia reasserted an old claim and invaded and seized Silesia. Charles Albert, Elector of Bavaria, claimed to be rightful heir to the Hapsburg possessions as a descendant through the female line of Ferdinand I, and in virtue of old arrangements. Augustus III of Saxony and Poland put forward his claims as the husband of the eldest daughter of the Emperor Joseph I. The Bourbon courts of France and Spain seized the opportunity to make war upon Austria. England thereupon entered into an alliance with Maria Theresa. Charles Emmanuel III of Sardinia was also among the princes who sought to dismember the Austrian realm. Holland joined the Anglo-Austrian Alliance, and the Bourbon King of Naples joined the enemies of Maria Theresa. Some minor German princes engaged in the struggle, as allies of Prussia and France. On April 10, 1741, Frederick II defeated the Austrians at Mollwitz. The Bavarians, the French, under Belleisle, and the Saxons poured into the Austrian dominions. Maria Theresa appealed for support to her Hungarian subjects at the Diet assembled at Pressburg and they responded chivalrously to her call, but she was unable to save Prague, which surrendered to Belleisle Nov. 26, 1741; yet at the beginning of 1742 her forces entered upon a victorious campaign against Charles Albert. General Khevenhüller overran Bavaria, and on the day of the Elector Charles Albert's coronation as Emperor Charles VII took Munich (Feb. 12, 1742). On May 17, 1742, Frederick won a victory over the Aus-

trians at Chotusitz, followed by the Treaty of Breslau (terminating the first Silesian War), which provided for the cession of most of Silesia to Prussia. The French General Belleisle retreated from Prague.

In May, 1743, Bavaria again fell into Austrian hands. In June the English, under George II, defeated the French at Dettingen. In the same year Saxony and Sardinia were won to the side of Austria. France and Spain now remained sole representatives of the coalition. Seeing the tide turn strongly in favor of Austria, Frederick became alarmed and renewed hostilities in 1744 by an invasion of Bohemia (second Silesian War). In January, 1745, Charles VII died and his son, Maximilian Joseph, made peace with Austria. On June 4, 1745, Frederick won a victory over the Austrians at Hohenfriedberg, and on December 15 the Prussians defeated the Saxons at Kesselsdorf. Frederick, displeased with the overbearing conduct of France, was willing to make terms with Austria, and the Peace of Dresden (Dec. 25, 1745) between Austria, Saxony, and Prussia terminated the second Silesian War. On Sept. 13, 1745, the husband of Maria Theresa had been elected Emperor as Francis I. Meanwhile the French were being led to victory in the Austrian Netherlands by Marshal Saxe, who, on May 11, 1745, defeated the English, Hanoverians, Dutch, and Austrians at Fontenoy. The principal towns of the region fell before his attacks, and on Oct. 11, 1746, he won a victory over the allies under Charles of Lorraine at Raucoux. In Italy the war was waged with varying fortune. In 1745 the French were successful. In 1746 the Austrians and Sardinians made a victorious advance, and Genoa, which had joined the enemies of Austria, was occupied. It was later evacuated, and an attempt to recapture it in 1747 was frustrated by the French. In 1747 Saxe routed the Duke of Cumberland at Laffeld, near Aix-la-Chapelle (July 2), while his chief of engineers, Count Löwendal, after a two months' siege, took Bergen-op-Zoom, a fortress believed by the Dutch to be impregnable. On the sea, however, the English gained victories in 1747 under Admirals Anson and Hawke. At this juncture the Empress Elizabeth of Russia came to the aid of Maria Theresa and sent forces into the field. France was now ready for peace. On Oct. 18, 1748, the Treaty of Aix-la-Chapelle ended the war. It left the Hapsburgs in possession of hereditary dominions, excepting Silesia. Parma and Piacenza (acquired in 1735) were ceded by Austria to Don Philip, brother of Ferdinand VI of Spain. The principal event of the contest waged by the British and French in America (King George's War) was the taking of Louisburg in 1745. The French held their ground in India. Consult: Deroy, *Beiträge zur Geschichte des oesterreichischen Erbfolgekriegs* (Munich, 1883); Franz Crousse, *La guerre de la succession dans les provinces belgiques* (Paris, 1885); Francis Parkman, "A Half Century of Conflict," in *France and England in North America*, part vi (2 vols., Boston, 1903); F. H. Shrine, *Fontenoy and the War of the Austrian Succession* (London, 1906); *Cambridge Modern History*, vol. vi (New York, 1909), containing a bibliography.

**War of the Bavarian Succession.** The Elector Maximilian Joseph of Bavaria died without issue on Dec. 30, 1777. The natural heir was Charles Theodore, Elector Palatine,

head of the elder line of the house of Wittelsbach.

This prince had no legitimate heirs, and with a view to the interests of his illegitimate children, he had, in January, 1778, entered into a convention with the Emperor Joseph II (the son of Maria Theresa, sovereign of Austria and Queen of Hungary) by which he agreed to transfer Lower Bavaria to Austria, which put forward an old claim to a part of Bavaria. Frederick the Great would not consent to aggrandize Austria in south Germany, as he felt that it might interfere with the claim of Prussia to the succession in the principalities of Ansbach and Bayreuth. As Austria refused to withdraw her pretensions, Frederick proceeded to make war on her, and in 1778 invaded Bohemia. He was joined by the Elector of Saxony, who, as the husband of the only daughter of Maximilian Joseph, claimed part of the Bavarian inheritance. Maria Theresa and Joseph II were in no haste to go to war with Prussia, and the Austrian forces confronted the enemy without coming to an engagement. The hostile attitude of Catharine II of Russia towards Austria induced her to give way, and in the Treaty of Teschen, signed on May 13, 1779, she had to content herself with the acquisition of the Innviertel, a district on the east side of the Inn, with the exception of which the whole of the Bavarian inheritance passed to Charles Theodore. The Elector of Saxony received a money indemnity. Consult C. Reimann, *Geschichte des bayrischen Erbfolgekriegs* (Leipzig, 1869).

**SUCCINIC** (sük-sin'ik) **ACID** (from Lat. *succinum*, *sucinum*, amber),  $\text{COOH} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{COOH}$ . A dibasic organic acid found in amber, in unripe fruits, in brown coal, etc. Small quantities of it are invariably produced in the alcoholic fermentation of sugar by yeast, the protein of the yeast cells undergoing slight decomposition with formation of succinic acid. In the animal organism succinic acid occurs in the spleen, the hydrocephalic and hydrocele fluids, and, according to some authors, also in normal urine. It has been known to chemists since the sixteenth century, and its acid character was discovered by Lemery in 1679. It may be obtained by a variety of synthetic chemical methods. Usually, however, it is prepared by the fermentation of a solution of ammonium tartrate. It is a crystalline substance melting at  $184^\circ \text{C}$ . ( $263^\circ \text{F}$ .) and boiling at  $235^\circ \text{C}$ . ( $455^\circ \text{F}$ .), though when distilled it loses the elements of water and is partly converted into its anhydride. Succinic acid is almost insoluble in ether; it is moderately soluble in cold and very soluble in hot water and alcohol. See **MALIC ACID**.

**SUC'CORY**. Another name for chicory (q.v.).

**SUC'COTH** (Heb. *sukcôth*, booths, thickets). The name of two places mentioned in the Bible. 1. In Josh. xiii. 27 a Succoth is described as situated in the territory of Gad, "in the valley," and within the ancient bounds of the territory ruled by Sihon, King of Heshbon. A location east of the Jordan is indicated here and also in Gen. xxxiii. 17 and Judg. viii. 5-16 (cf. Ps. lx. 6, cviii. 7). In 1 Kings vii. 46 (2 Chron. iv. 17) it is stated that the metal work for Solomon's temple was cast "in the plain of Jordan between Succoth and Zarethan." A site south of the Jabbok (Nahr el Zerka) seems to be demanded. 2. Succoth was also the name of the second station in the Exodus from Egypt

(Ex. xii. 37, xiii. 20; Num. xxxiii. 5-6), which has been connected with *Thulcu*, the Egyptian name of a district in the eastern delta and of a fortress in it. Consult G. F. Moore, *Judges* (New York, 1895), and B. Stade, *Die Entstehung des Volkes Israel* (Giessen, 1897).

**SUC'COTH-BE'NOTH**. According to 2 Kings xvii. 30, the name of a deity whose worship was carried on in the cities of Samaria by the colonists from Babylon settled there by the King of Assyria. No such god has been found in Babylonian inscriptions, and it is reasonable to conclude that the form is a corruption of Zarpanit, the wife of Marduk (q.v.).

**SUC'CUBA**. See **INCUBUS**.

**SUCHER**, zû'kër, JOSEF (1844-1908). A prominent Austrian musical conductor, born at Döbör, Eisenburg County, Hungary. First instructed in music as a chorister in the Imperial chapel at Vienna, he afterward studied law at the university and composition under Sechter, became conductor of the Akademische Gesangverein and assistant conductor at the opera, and in 1876 went to Leipzig as kapellmeister at the Stadt Theater, where his rehearsals of Wagner's music dramas, especially of the *Ring of the Nibelung*, placed him in the front rank of modern conductors. In 1879 he was called to Hamburg and in 1888 to the Royal Opera in Berlin. He retired in 1899, and spent the remaining years of his life in the German capital. For his wife, see **SUCHER, ROSA**.

**SUCHER, ROSA** (HASSELBECK) (1849-1927). A German dramatic soprano, born at Velburg, Upper Palatinate. She appeared first in Munich, was subsequently connected with the stages at Treves, Königsberg, and Danzig, then at Leipzig, where she was married to Josef Sucher (q.v.). With her husband she went to Hamburg and Berlin. She was one of the foremost interpreters of Wagner's heroines, frequently appearing at Bayreuth. In 1895 she was a member of Mr. Damrosch's German opera company in the United States. She retired from the stage in 1898.

**SUCHET**, sü'shâ', LOUIS GABRIEL, Duke of Albufera (1770-1826). A marshal of France and one of the best of Napoleon's generals, born at Lyons, March 2, 1770. He began his career by volunteering as a private in the Lyons National Guard in 1792. His intelligence and valor at Lodi, Rivoli, Castiglione, and Arcole laid the foundation of his military reputation. In 1797 he became a general of brigade and the next year general of division, serving in Switzerland and Italy. In 1880 he kept Melas in check, with a force less than the Austrians, and prevented the invasion of France. He took part in the campaigns against Austria (1805) and Prussia (1806-07), was sent to Spain in 1808, and in 1809 was appointed to the command of the French army in Aragon. He won the battle of Belchite (June 16-18, 1809) and took Lérida (May, 1810), and Tortosa and Tarragona (1811), earning the marshal's baton. In January, 1812, he conquered Valencia, and became Duke of Albufera. The misfortunes of the other French armies in Spain compelled Suchet gradually to relinquish his conquests. He was created a peer by Louis XVIII, but took service under Napoleon after Elba, and was charged with the defense of the southwestern frontier. Deprived of his peerage at the Second Restoration, he did not return to court till 1819. He died near Marseilles, Jan. 3, 1826. Consult Suchet, *Mé-*

moires sur ses campagnes en Espagne (Paris, 1829-34).

**SUCHIER**, sy'shyä', HERMANN (1848-1914). A German romance philologist, born at Karlsruhen, on the Weser, of a family of French refugees. After studying at Marburg and Leipzig, he qualified as privatdocent at Marburg in 1873 and became successively assistant professor at Zurich (1875), and professor at Münster and Halle (1876). Of his publications in the field of French and Provençal philology may be noted: "Die französische und provenzalische Sprache und ihre Mundarten," in Gröber's *Grundriss der romanischen Philologie* (1888; 2d ed., 1906), also separate in French, *Le Français et le Provençal* (1891); *Altfranzösische Grammatik* (1893), also in French under the title *Les voyelles toniques du vieux français* (1906). He edited *Aucassin et Nicolette* (1878; 8th ed., 1913); *Bibliotheca Normannica* (8 vols., 1879-1911); *Denkmäler provenzalischer Litteratur und Sprache* (1883); *Œuvres poétiques de Beaumanoir* (2 vols., 1884-85); *Les Narbonnais* (2 vols., 1898); *La Chancune de Guillaume* (1911). In collaboration with Birch-Hirschfeld he wrote a *Geschichte der französischen Litteratur* (1900; 2d ed., 1913). In 1900 a *Festgabe* entitled *Forschungen zur romanischen Philologie* was presented to him by his pupils.

**SUCHOW**, sū'chou', or **SOOCHOW**. A fu or departmental city of the Province of Kiangsu, China (Map: China, M 5); the residence of the provincial judge, the *chih-fu* or head of the department of the same name, and three district magistrates. It is situated on the Grand Canal, 80 miles west of Shanghai and 40 south of Yangtse. Its walls are 30 feet high, are pierced with 6 gates and 5 water gates, and have a circuit of 12 miles. Outside of five of these gates are large suburbs, the largest and busiest being that outside of the northwest gate or Ch'ang-mên, within which is the chief business quarter of the city. Suchow was founded about 500 B.C. It is the centre of a great silk and satin industry in which thousands of looms are employed, has also steam factories, two cotton mills, a flour mill, and thousands of workers in wood, gold, silver, brass, iron, tin, ivory, glass, lacquer, etc. It has long been noted for its wealth and luxury, and the gayety and elegance of its life and manners. In 1860 it was captured by the Taiping rebels and reduced almost to a heap of ruins. Among the buildings that escaped destruction is a pagoda 240 feet in height, said to be the highest in China. The streets of the city of Suchow are not wide enough for much traffic, but a great network of canals furnishes easy means of transportation between the city and the surrounding country. Pop. (est.), about 500,000.

In September, 1896, Suchow was opened by treaty as a place of foreign residence and trade. In 1912 imports amounted to 2,634,273 Hk. taels, and exports to 8,736,307 taels (Haikwan Tael = \$0.726).

**SUCKER** (from *suck*, AS. *sūcan*, *sūgan*, OHG. *sūgan*, Ger. *saugen*, to suck; connected with Lat. *sugere*, to suck). A fresh-water fish of the catfish family and belonging to the genus *Catostomus* and its allies, characterized by having the mouth inferior, and the lips thick and fleshy, the lower usually deeply divided. There are many species, all of moderate size and natives of the United States, except one in Siberia. Their general form is shown in the Plate of

**SUCKERS**; in color they are dull, and with little tendency to markings, except that breeding males in most species acquire a rosy or orange lateral band. They inhabit rivers, lakes, and bayous, and obtain their food mostly by sucking up the mud and soft organic matter from the bottom. The most widely distributed species is the northern or red sucker (*Catostomus catostomus*); the best known one, the common white sucker (*Catostomus commersonii*), which is abundant from Massachusetts to Kansas.

**SUCKER STATE**. Illinois. See STATES, POPULAR NAMES OF.

**SUCKING FISH**. See REMORA.

**SUCKLING**, SIR JOHN (1609-42). An English poet, born at Whitton, in Middlesex, where he was baptized Feb. 10, 1609. His father, Sir John Suckling (knighted 1616), held high posts at the courts of King James and King Charles. In 1623 the poet entered Trinity College, Cambridge, but left without a degree. On the death of his father in 1627 he became heir to large estates. In 1628 he set out on extensive travels on the Continent and is said to have fought under Gustavus Adolphus. Returning to England in 1632, he soon became noted for wit, gallantry, and prodigality. Suckling took an active part in the plot to rescue Strafford from the Tower, and found it convenient to flee to the Continent. Impoverished and in despair, he seems to have poisoned himself in Paris in the summer of 1642. He was buried, says Aubrey, in the cemetery of the Protestant Church in Paris. Suckling's writings, few of which were published during his lifetime, were collected under the title *Fragmenta Aurea* (1646). The volume contains three plays, "Aglaura," "The Goblins," and "Brennoralt; Letters to Divers Eminent Personages"; a Socinian tract called "An Account of Religion by Reason"; and "Poems." In a later edition (1658) appeared an unfinished tragedy, "The Sad One." The fame of Suckling rests wholly upon his lyrics, inimitable for grace and gayety. Consult *Selections*, with a memoir, by A. I. Suckling (London, 1836; revised and enlarged by W. C. Hazlitt, under title of *Poems, Plays, and Other Remains*, 2d ed., 2 vols., ib., 1892), and *Works*, edited by A. Hamilton Thompson (New York, 1910); and see the articles on the group of cavalier or court poets to which Suckling belongs: THOMAS CAREW; ROBERT HERRICK; RICHARD LOVELACE.

**SUCRE**, sū'krä. A department of Bolivia. See CHUQUISACA.

**SUCRE**. The official capital of the Republic of Bolivia, known also as Chuquisaca (Map: Brazil). It is 9328 feet above the sea on a plateau of the eastern Cordillera of the Andes, and is 318 miles southeast of La Paz. It has the Supreme Tribunal of Justice. The principal buildings are the cathedral and the president's palace. There is an ancient university with faculties of law, medicine, and theology. Its industries are mining and agriculture, the latter being the more important. Pop. (est.), 24,000. Sucre, founded in 1536 by Spaniards, and named La Plata from the rich silver mines of the vicinity, was later the seat of the *audiencia* of Charcas, serving as the capital of Upper Peru. The city was the scene of the declaration of Bolivian independence from Spain, Aug. 6, 1825, and later took the name of Sucre in honor of the republic's first president. Though it has continued to be the official capital of Bolivia,

1. RAZOR-BACKED SUCKER (*Xyrauchen cypho*).
2. CHUB SUCKER (*Erimyzon sucetta*).
3. MISSOURI SUCKER (*Cycleptus elongatus*).

4. MAY SUCKER, or CUTLIPS (*Lagochile laceri*).
5. MOUTH OF CUTLIPS (No. 4).
6. CARP SUCKER (*Carpiodes cyprinus*).
7. BUFFALO FISH (*ictiobus cyprinella*).

the sessions of Congress, during the civil wars, have often been held at La Paz.

**SUCRE**, ANTONIO JOSÉ DE (1793-1830). A Venezuelan general, born at Cumaná, and educated at Carácas. He served in the various wars of independence in South America, from 1811 to 1824, was one of Bolívar's most valuable officers, and gained the victories of Pichincha (May 24, 1822), which freed Ecuador, and Ayacucho (Dec. 9, 1824), which drove the Spaniards from Peru. At the first election of the Republic of Bolivia, Sucre was chosen life president (1826). He failed in his effort to establish an orderly government, and resigned in 1828 at the demand of Peru. He returned to Colombia, entered the army and won from the Peruvians the decisive battle of Girón (Feb. 26, 1829). On his return to Quito from a session of the constituent Congress of Colombia, of which he was president, he was assassinated, supposedly by his political enemies (June 4, 1830).

**SUCTION DREDGE.** See DREDGE.

**SUDAN**, *sū'dān'* or *sū-dān'*, or **SOUDAN**. A term designating the vast region in north Africa lying between the Atlantic and the Red Sea, and between the Sahara Desert, on the north, and the Gulf of Guinea and the watersheds between Lake Chad and the Congo and between the Nile and the Congo, on the south. The northern line is about lat. 18° N., the southern about 4° N. The Sudan is the short form of Beled-es-Sudan, "Land of the Blacks." The name is sometimes limited to the grass belt lying between the Sahara on the north and the forest belt to the south. Except Portuguese Guinea, Togoland and Kamerun, and Liberia, all of the Sudan is now virtually divided up between Great Britain and France. To Great Britain belong Gambia, Sierra Leone, the Gold Coast, Lagos, and Nigeria (northern and southern); the government of the Egyptian Sudan is shared by England and Egypt; and Darfur is within the British sphere of influence. (See **SUDAN**, **ANGLO-EGYPTIAN**.) Under French control are Senegal, French Guinea, the Ivory Coast, Dahomey, French Congo, Bagirmi, and Wadai. The French Sudan (q.v.) was formerly the name of the territory in West Africa lying between long. 12° W. and Lake Chad and between the Sahara on the north and the countries along the north coast of the Gulf of Guinea. By the decree of Oct. 17, 1899, French Sudan ceased to exist. The western portion fell to Senegal, French Guinea, the Ivory Coast, and Dahomey. The remainder was formed into the two territories of French West Africa (q.v.), Upper Senegal and Niger and the military territory of the Niger. All the above French possessions, except French Congo, Bagirmi, and Wadai, are included in the governor-generalship of French West Africa (q.v.) formed in 1895, which also embraces practically all of the Sahara (q.v.), in accordance with the decree above named; for Great Britain has recognized the claims of France to all the region west of the Nile basin, embracing substantially all of the Sahara Desert (excluding the Libyan Desert).

For particulars as to topography, climate, commerce, races, etc., see articles on the different countries mentioned.

**Ethnology.** Within this broadest belt of Africa lying south of the Sahara, the following races and peoples are to be discriminated:

1. Semites, consisting of Arabs, who under many names live in Kanem and Bornu about

Lake Chad and eastward to Khartum and Kordofan.

2. Hamites, whose main divisions are the Tibus, in many subdivisions, about Lake Chad; the Tuaregs, within the Niger bend and on the left bank of the Senegal; and the Fulah, Futa-Toro, and Futa-Jallon, scattered from Senegambia to Darfur and south to Adamawa.

3. Negroes, who are best divided into three provisional geographical groups. The western Sudanese include the Wolof, Serer, Sarakole, Toucouleur, Mandingo, Felup, and innumerable other tribes from the Senegal River to Sierra Leone; the Sierra Leone negroes, comprising the Temne family and a multitude of pagan tribes; the Liberian negroes, or Colonials, Kru, and many pagan tribes; the Ivory Coast negroes, from Cape Palmas eastward, akin to the Kru; the Gold Coast negroes, composed of the Tshi group, including the Fanti, Ashanti, and others, and the Ga groups, all pagans; the Slave Coast negroes, making up the Ewe group, including the Dahomans (see **DAHOMY**), and the Yoruba group. The central Sudanese comprise the Niger Basin negroes, including the Bambarra, Sonrhay, and Hausa (see **HAUSA STATES**); the Benue negroes, composed of Moslem and pagan tribes in the region of the Benue River; the lower Niger negroes, or the Ibos (Niger delta), the Igbara (above the Benue confluence), and a multitude of pagan and Moslem tribes; the Chad Basin negroes, comprising the Kanuris, the Baghirmi, the Mosgu, and many thousands of others chiefly pagan and mixed with Semites and Hamites; the Wadai negroes, including the Maba and many other tribes all of more or less mixed blood, with a large percentage of Moslems; the Darfur and Kordofan negroes, or Furs (Moslems), and Nuba (pagans). The eastern Sudanese include the Nilotic or Dinka upper Nile negroes, extending from Lake Victoria northward, and including the Madi, the Mittu, Shilluk, and a host of others, nearly all pagan; the Welle negroes, comprising the Mangbettu, the Momfu, the Azande (Niam Niam), and a number of other tribes.

**History.** The Anglo-Egyptian Sudan is practically coincident with the ancient Nubia (q.v.). The eastern Sudan was brought under Egyptian control by Mehemet Ali (q.v.) in 1820-22 and so remained until in 1870 Ismail Pasha found it necessary to ask for assistance in restoring the waning authority of the khedival government in the interior. The Englishman Sir Samuel Baker was made Governor-General of the Sudanese provinces and began their reduction and the suppression of the slave trade. He established his capital at Gondokoro, which he renamed Ismailia. Supposing that his work was accomplished, Baker returned to England. After his departure the slave trade was immediately revived and the administration of the provinces was intrusted to Charles George Gordon (q.v.), who began the organization and development of this rich but little-known region. Gordon continued his work in the face of all manner of discouragements and difficulties until his recall in 1879 upon the deposition of Ismail, and, though Gordon's organization was continued under his successor, Rauf Pasha, there was a gradual reversion to earlier conditions. In 1882 the Sudanese tribesmen, for a long time restless under the greed and misgovernment of the Egyptian officials, took advantage of the difficulties in Lower Egypt and revolted. This, like the

rising under Arabi Pasha (q.v.), with which it coincided in point of time, was primarily a revolt against foreign influence, but, unlike the latter, which was a political movement, it had its immediate origin in religious fanaticism. England had become so deeply involved in Egyptian affairs that she was compelled to take part in this struggle for the control of the upper Nile country. A force of 11,000 English and Egyptian troops was dispatched to the Sudan under Hicks Pasha. This force was annihilated in a battle with the tribesmen at El Obeid (Nov. 3-4, 1883). England then determined to abandon the Sudan, but several posts were held by British garrisons and it was necessary to withdraw these troops. For this difficult task and for the settlement of the troubled affairs of the country, Gordon, because of his former success and his knowledge of the tribesmen, was given a new commission as Governor-General, and on Feb. 18, 1884, he arrived at Khartum. In the meanwhile Osman Digna (q.v.) was making his power felt in the vicinity of Suakim, which became the scene of bloody fighting, Osman Digna being finally defeated (February-March, 1884). Gordon was surrounded at Khartum by the Mahdi's forces and cut off from all of his communications. After many delays, in part due to the fatal hesitation of the Gladstone government, a relief force was sent out under Lord Wolseley, which after severe fighting arrived at Khartum, Jan. 28, 1885. Two days previously the city had been captured and Gordon killed. The English then retired and until 1894 gave up the attempt to reconquer the revolted provinces; but the growing British interest in east and central Africa made it inevitable that England should seek to control a position of so great strategic importance. Upon the death of the Mahdi in 1885 his power passed to his chief lieutenant, the Khalifah Abdallah. In the interval of peace the Egyptian army was reorganized and brought to an admirable state of discipline under its English officers, and in 1894, under the Sirdar, Sir Herbert Kitchener (q.v.), the struggle for the possession of the Sudan was resumed. This movement was stimulated by the threatened movement of Osman Digna (q.v.), the ablest Dervish leader, upon the Italian post at Kassala, where a victory might throw the Dervishes again upon the Egyptian frontier. After slow and patient preparation the advance up the Nile was made and Dongola was captured, Sept. 23, 1896. Pushing forward his railway across the desert at the rate of about two miles a day, General Kitchener advanced steadily, always maintaining communication with his base on the Nile. The Khalifah was gradually hemmed in and on Sept. 2, 1898, at Omdurman, opposite Khartum, he was defeated, his army annihilated, and his power completely broken. He himself was killed near Gedid in November, 1899.

The French had sent out a tentative expedition under Major Marchand (q.v.) to Fashoda, with a view to entering a wedge of French influence in the eastern Sudan, but the French were themselves threatened by the tribesmen and were rescued by General Kitchener a few days after the victory at Omdurman. The aggressive attitude of England forced France to enter a diplomatic disclaimer. This led to the recognition by France in the supplementary treaty of 1899 of the English sphere of influence in the Sudan from Darfur and the Bahr el

Ghazal eastward. By the Anglo-Egyptian convention signed Jan. 19, 1899, the government of the Sudanese provinces was to be intrusted to a governor general appointed by the Egyptian government with the approval of the British government, the slave trade was prohibited, as well as the importation of arms and ammunition, and the British and Egyptian flags were to be used conjointly.

Stevens, *With Kitchener to Khartum* (new ed., ib., 1914).

**SUDAN, ANGLO-EGYPTIAN.** That part of northeast Africa, under Anglo-Egyptian control, lying south of Egypt (Map: Africa, G, H 3). The total area is given as approximately 985,000 square miles. The distance from the Egyptian boundary to Lake Albert is 1400 miles. In the north lies the Nubian Desert, and across the central section and in the extreme south are found mountains. In the flat part of the southern region are pestilential swamps. In this section the rainfall is enormous, being from 80 to 100 inches a year. There are only two dry months—November and December. The precipitation gradually diminishes northward, and represents about an average fall at the northern boundary of the country. The Nile, with its important head streams, courses through the entire land from Lake Albert to Egypt. All the tributaries of the Nile enter it in Egyptian Sudan. (See NILE.) The Atbara is heavily charged with volcanic debris from the Abyssinian highlands, and supplies the greater part of the mud which gives fertility to Lower Egypt. Egyptian Sudan is largely underlain by igneous and metamorphic rocks. Of these materials are composed most of the ranges and ridges traversing this region. To the northwestward the formations become successively younger in geologic age. The country is not only well watered, but the extremes of temperature are

not excessive, though the mean temperature is high. But agriculture suffered greatly after the revolt of the Mahdi in 1883, and trade was largely abandoned. In December, 1889, the Territory was reopened for trade, and the important traffic of former times in ivory, ostrich feathers, gold dust, gums, and skins is being revived. The opening in January, 1906, of the Berber-Suakin railway, a distance of over 200 miles, is of the utmost advantage to the Sudan, as it gives it a short route to the sea. In the south particularly there are great natural resources. The soil along the White Nile is rich, and millet, durra, and sesame are raised. The forests are extensive, and possess numerous valuable varieties of wood.

The region is divided into 13 provinces—Khartum, Dongola, Berber, Kassala, Sennar, Kordofan, Blue Nile, White Nile, Bahr el Ghazal, Halfa, Red Sea, Mongalla, and Upper Nile. For 1912 the receipts were estimated at £1,375,600, the expenditures £1,568,600. Population was given as 10,000,000 before 1882, but fully four-fifths of the inhabitants are thought to have perished during the Dervish rule. Pop., 1914 (est.), 3,000,000. Khartum (q.v.) is the capital, and is connected with Cairo by rail and telegraph. Other chief towns are Omdurman, Dongola, Wadi Halfa, Berber, Kassala, El Obeid, and Suakin. Population of Khartum, with suburbs, 70,000 in 1910; of Omdurman in 1912 approximately 48,000. See SUDAN and bibliography there given.

**SUDAN, MILITARY TERRITORIES OF FRENCH.** See MILITARY TERRITORIES OF FRENCH SUDAN.

**SUDAN GRASS** (*Andropogon sorghum sudanensis*). This promising hay grass was introduced into the United States in 1909 from Khartum, where it appears it was cultivated under the name garawi. It is closely related to Johnson grass (q.v.) but unlike that species it has no perennial rootstock and, as a consequence, it is not liable to become a pest. It has been given trial over a large part of the country and for the semiarid portions of the United States it has been found a valuable acquisition. As generally grown in the United States it is treated as an annual but in frostless regions it becomes perennial in its habit of growth. Sudan grass ratoons well and several cuttings may be had in a season. In Hawaii it is considered one of the most valuable grass introductions ever made. Tunis grass, another form of *Andropogon* without underground rootstocks, is less leafy and not so vigorous in habit of growth as Sudan grass. See ANDROPOGON.

**SUD'BURY.** A town and the capital of Sudbury District, Ontario, Canada, on the Canadian Pacific, Canadian Northern, and the Algoma Eastern railways (Map: Ontario, E 1). It is the centre of a famous nickel district. A Jesuit College and government school of mines are located here. Pop., 1901, 2027; 1911, 4150.

**SUDEBNIK.** A Russian code of laws. The first sudebnik was compiled in 1497 under the direction of Ivan III and was the first attempt to systematize the rules of court procedure that had grown up during the preceding centuries. The first sudebnik was necessarily fragmentary. During the years 1550-51 a second sudebnik was prepared under the supervision of Ivan IV, which has remained the authoritative source of Russian law for that period.

**SÜDENHORST, HANS ZWIEDINECK VON.** See ZWIEDINECK VON SÜDENHORST, HANS.

**SUDERMANN, zŭ'dér-män, HERMANN** (1857- ). A German dramatist and novelist, born at Matzicken, East Prussia, Sept. 30, 1857. He studied history, philology, and literature at Königsberg and Berlin. After some obscure years as tutor and journalist he published the small collection of stories *Im Zwielicht* (1887), but won European fame and assured literary position by a drama *Die Ehre* (1888), and the novel *Frau Sorge* (1888; trans. as *Dame Care*, 1892). He followed these up with the novel *Der Katzensteg* (1889; trans. as *Regina*, 1898); the sensational drama, *Sodoms Ende* (1890); the humorous short story *Iolanthes Hochzeit* (1893); and his greatest drama, *Heimat* (1893; trans. as *Magda*, 1895); a fine novel of moral psychology, *Es war* (1894); an inferior drama, *Die Schmetterlingsschlacht* (1894); and *Das Glück im Winkel* (1896), a strong but unpleasant play. Then came three one-act dramatic scenes in verse collected under the appropriate title *Morituri* (1896); *Johannes* (1897), a realistic dramatic presentation of the story of John the Baptist; *Die drei Reihfeder* (1898), an ethical and literary mystery in dramatic form; *Johannisfeuer* (1901); *Es lebe das Leben* (1902; trans. *The Joy of Living*, 1902), a powerful drama of the struggle between soul affinity and marital obligation; *Der Sturmeselle Sokrates* (1903); *Stein unter Steinen* (1905); *Das Blumenboot* (1905); *Rosen* (1907), four one-act dramas; *Strandkinder* (1909); *Der Bettler von Syrakus* (1911); and *Der gute Ruf* (1912). Sudermann's work with the dramas of Hauptmann is the most significant in contemporary Germany, powerful in conception, admirable in technique, virile in its grasp of humanity in the more sombre aspects, and with occasional touches of delicate humor, though Sudermann is more skilled with the sterner weapons of satire. *Frau Sorge* is a pathetic Odyssey of duty with some romantic aberrations; *Katzensteg* is a declaration of "naturalism"; *Iolanthes Hochzeit* breathes the serene realism of common life; *Es war* is a protest against the fruitlessness of brooding repentance. The dramas *Die Ehre*, *Sodoms Ende*, and *Heimat* are all social satires and militant democratic protests. By comparison the later dramas are increasingly out of touch with modern life. In *Die drei Reihfeder* the evolution has become complete transformation. To some it seems a deepening, to others a sinking of his dramatic power.

Sudermann made a wide appeal both at home and abroad. Many of his books ran into scores of editions; in the case of *Frau Sorge* the 125th edition was reached in 1912. His greater works have appeared in English translation.

**Bibliography.** George Brandes, *Menschen und Werke* (2d ed., Frankfurt, 1895); Berthold Litzmann, *Das deutsche Drama* (2d ed., Hamburg, 1894); W. Kawerau, *H. Sudermann* (Magdeburg, 1897); Hans Landsberg, *H. Sudermann* (Berlin, 1902); Maximilian Harden, *Kampfgenosse Sudermann* (ib., 1903); J. G. Huneker, *Iconoclasts* (New York, 1905); E. E. Hale, *Dramatists of To-day* (ib., 1905); Otto Heller, *Studies in Modern German Literature* (Boston, 1905); Ida Axelrod, *Herman Sudermann: eine Studie* (Stuttgart, 1907); Karl Knortz, *Sudermanns Dramen* (Halle, 1908); W. L. Phelps, *Essays on Modern Novelists* (New York, 1910).

**SUDETIC MOUNTAINS** (Ger. *Sudeten*).

A mountain system on the south border of Silesia, Germany, which some of its ranges separate from Bohemia and Moravia (Map: Germany, G 3). It extends in a southeast direction from the water gap of the Elbe to the "Moravian Gate," a gap through which the Oder passes, and which separates the system from the Carpathian Mountains. The system is composed of a number of short, broken, more or less isolated and partly parallel ranges, consisting chiefly of crystalline slate, serpentine, and granite. These ranges inclose a number of large valleys. The best defined as well as the highest of the ranges, the Reisingebirge, lies near the centre of the system, and attains an average altitude of 4250 feet, culminating in the Schneekoppe, 5255 feet above the sea. The higher ridges have an alpine flora appearing above the large pine forests which cover the slopes. Many of the slopes afford fine pasturage for sheep and the foothills are well cultivated. The Sudetic Mountains are very rich in minerals, especially iron, zinc, lead, and copper, and in the southeastern portion there are large coal deposits.

**SUDHAUS**, zoot'hous, SIEGFRIED (1863-1914). A German classical scholar, born at Treptow. He studied at Bonn and Berlin, and taught at Bonn from 1888 till 1901, when he became professor at Kiel. In 1912 he was rector of the university. He was killed in battle in Russian Poland in November, 1914. His publications include: *Philodemi Volumina Rhetorica* (1892-96); *Aetna* (1898); *Der Aufbau der Plautinischen Cantica* (1909); *Menandri Reliquiae* (1909).

**SUDHOFF**, zoot'hof, KARL (1853- ). A German physician and medical historian, born at Frankfort-on-the-Main. He studied medicine at Erlangen, Tübingen (M.D., 1875), Berlin, and Vienna, and practiced at Bergen and later at Hochdahl. In 1905 he was called to the University of Leipzig to be professor of the history of medicine, a chair created for him through the Theodor Puschmann (q.v.) foundation. Sudhoff wrote many important essays on the history of medicine, especially on Paracelsus and Paracelsian manuscripts, on the iatromathematicians of the fifteenth and sixteenth centuries, on German medical incunabula, on the Greek medical papyri of the Alexandrian period, and on the early history of syphilis. He published the *Klassiker der Medizin* (1910 et seq.), a collection of reprints of classical medical works, and became editor of *Studien zur Geschichte der Medizin*.

**SUDORIFICS**. See DIAPHORETICS.

**SUDRA**, sho'dra. See CASTE.

**ŚUDRAKA**, sho'drā-kā. A Hindu king to whom tradition attributes the Sanskrit drama *Mricchakatikā* (q.v.), more probably composed by Dandin (q.v.). He seems to have been altogether mythical, for the only Śudraka found in the history of India is a king of Gaya who probably lived in the twelfth century. According to different legends he reigned either at Vidiśa, or Śobhavati, or Vardhamana. He is said to have recovered his eyesight through Siva's (q.v.) favor and to have lived more than 100 years. Consult Sylvain Lévi, *Théâtre Indien* (Paris, 1890); Montgomery Schuyler, *Bibliography of the Sanskrit Drama* (New York, 1906).

**SUE**, su, MARIE JOSEPH (KNOWN AS EUGÈNE) (1804-57). A French novelist, born in Paris.

He studied medicine, became an army surgeon, was transferred to the navy, cruised in the East, resigned in 1829, having inherited wealth, and gave himself successively to literature, dissipation, and socialistic agitation, writing *feuilletons* that rivaled those of Dumas in rapidity of production, fertility of imagination, and carelessness of execution. In 1831 he published *Plick et Plock*, the success of which led to *Atar-Gull* (1831), a novel of the sea, suggested by his own experience and by the American novels of Cooper. It revealed a gift of story-telling, but showed a reckless mingling of tragic and comic, pathetic and grotesque. Debts and disgust at his equivocal social position turned him into a socialist and convert to the propagandism of Fourier and Proudhon. His work in this spirit consists of long novels printed in cheap newspapers, but winning such hold on the masses that the government sought to check his activity. Sue entered on an unexplored path when he began the *Mystères de Paris* (1842). He was undertaking to paint the sufferings, the needs, the possibilities of the working class with the intent of influencing their political action, and he was for the novel a new audience and a new interest. He entered on the task with an enthusiasm that fired his genius to the creation of types of character that still have power to horrify or charm. Both the *Mystères de Paris* and *Le Juif errant*, "The Wandering Jew" (1844-45), were dramatized by Sue, and both have attained world-wide circulation. He wrote an *Histoire de la marine française* (1835-37) and two historical novels, *Latréaumont* (1837) and *Jean Cavalier* (1840). The later work of Sue is vast. He was elected to the Assembly in 1850, and was exiled in December, 1851. He died at Annecy in Savoy. Consult Eugène de Mirecourt, *Eugène Sue* (4th ed., Paris, 1870).

**SUECA**, swā'kā. A town of Spain, in the Province of Valencia, 23 miles south of the city of that name, on the left bank of the Júcar (Map: Spain, E 3). It is in a fertile valley. Pop., 1900, 14,422; 1910, 17,178.

**SUERA**, swā'ra. A seaport of Morocco. See MOGADOR.

**SUESS**, zus, EDUARD (1831-1914). An Austrian geologist. He was born in London, studied the natural sciences at Prague and Vienna, and from 1857 to 1891 was professor of geology at the University of Vienna. From 1873 to 1896 he was a member of the Austrian Lower House. From 1897 to 1911 he was president of the Imperial Academy of Sciences. His more important contributions to geology, which have opened up a new path in geological inquiry, and laid the foundation for what is now frequently termed the "new geology," deal with the construction and relations of continents and mountain ranges, the dynamics of volcanoes and earthquakes, and the general movements of the earth's crust. His *Antlitz der Erde* (1883-1901; Eng. trans., *Face of the Earth*, 1904-09) is a masterly exposition of the relation of the dominant features of the earth's surface, and the first luminous effort to correlate their multifiform aspects and give to them their true geographic expression. Among his other works are *Ueber den Löss* (1860) and *Die Entstehung der Alpen* (1875).

**SUETONIUS TRANQUILLUS**, GAIVS. A Roman historian, born probably a few years after the death of Nero. Pliny procured for him the dignity of military tribune, which, by

Suetonius's desire, was transferred to another. He was afterward secretary of the Emperor Hadrian. His death occurred about 160 A.D. All his works (among which, as we learn from Suidas, there were several on topics usually treated by grammarians) have been lost, except his *Lives of the Cæsars*, part of his *Lives of Eminent Grammarians*, and part of his *Lives of Eminent Rhetoricians*. The *Lives of the Cæsars* contains information about the 12 Cæsars, from Julius Cæsar to Domitian, which is to be had nowhere else, and abounds with anecdotes which, while they too often prove the profligacy of his heroes, or the pruriency of Suetonius's own mind, testify to the impartiality of their chronicler. The best editions are by Baumgarten-Crusius (Leipzig, 1816-18), Reifferscheid (ib., 1860), Roth (ib., 1886); and of parts, by Peck (New York, 1891), Schuckburgh (Cambridge, 1896), Ihm (Leipzig, 1907), and Pike (Boston, 1903). There is an English version by Thomson and Forrester (ib., 1855), and another by J. C. Rolfe (2 vols., New York, 1914). Consult the introduction in Schuckburgh's edition; Martin Schanz, *Geschichte der römischen Litteratur*, vol. iii (2d ed., Munich, 1905); W. S. Teuffel, *Geschichte der römischen Literatur*, vol. iii (6th ed., Leipzig, 1913); M. S. Dimsdale, *A History of Latin Literature* (New York, 1915).

**SUEVI.** The collective designation of a great number of Germanic peoples (Cæsar, *De Bello Gallico*, iv, 1). They occupied a district of indefinite extent on the eastern side of the Rhine, and may have been the same tribes as those subsequently known as Chatti, Longobardi, etc. Cæsar states that their territory comprised 100 cantons, and was densely wooded, that they had towns (*oppida*), but no strongholds, and that every year a part of the population left their homes to seek employment in war. The Suevi of whom Tacitus speaks (*Germania*, 38, etc.) seem to have dwelt north and east of the country of the Suevi of Cæsar, extending as far as the Elbe and the Baltic, which Tacitus calls the "Suevic sea." The peoples united under the rule of Maroboduus, the Marcomannic chief, were Suevic, and hence the Marcomanni (q.v.) and the Quadi (q.v.) who figure in the reigns of Marcus Aurelius and Aurelian are often called Suevi. After the name had fallen into disuse as a collective designation, it reappeared in Ammianus Marcellinus (q.v.) as the name of a people occupying the same territory as the Suevi of Cæsar. We find them in alliance with the Burgundians, Alemanni, Alani, Vandals, etc. They are among the most notable of the barbaric peoples that broke up the Roman Empire in the northwest and west. Bursting through the passes of the Pyrenees (409 A.D.), they, along with the Vandals, overran and wasted Spain (q.v.). Those who remained at home in Germany seem to have spread during the fifth century east of the Neckar and the Rauhe Alb, and south as far as Switzerland. The mediæval Swabians were their direct descendants. Consult the article "Sueben," in Friedrich Lübker, *Reallexikon des klassischen Altertums*, vol. ii (8th ed., Leipzig, 1914).

**SUEZ, sōō-ēz'.** A town of Egypt, situated on the south coast of the Isthmus of Suez, at the north extremity of the gulf of that name, and near the southern terminus of the Suez Canal (Map: Egypt, C 1). It is built on a desert peninsula, and consists chiefly of unpretentious-

looking houses. The European quarter, however, is regularly laid out, and contains the large warehouses of the Peninsular and Oriental Steamship Company. There are also a large English and a French hospital, and the town is supplied with water from the Nile at Cairo through a fresh-water canal. To the south a large stone causeway, carrying a railroad, runs to the immense harbor of Port Ibrahim, at the entrance to the canal, 2 miles south of the town. Suez has railroad connection with Cairo and Ismailia, but its commerce is not very large, as only a small portion of the transit trade passing through the canal affects the town. Pop., 1907, 18,347.

**SUEZ, GULF OF.** An arm of the Red Sea between the Sinai Peninsula and the main portion of Egypt (Map: Egypt, C 2). It has a length of 187 miles with a breadth of from 14 to 39 miles. At its north end, which is the extreme north end of the Red Sea, it is artificially connected with the Mediterranean Sea by the Suez Canal (q.v.).

**SUEZ, ISTHMUS OF.** The neck of land connecting the Sinai Peninsula with the main land of Egypt, and separating the Mediterranean from the Red Sea (Map: Egypt, C 1, 2). The shortest straight-line distance across it, between the site of the ancient Pelusium and the head of the Gulf of Suez, is 72 miles. The isthmus consists of a low, sandy, and stony desert, the lowest depressions being occupied by salt lakes and marshes, and it is almost wholly destitute of fresh water. A series of such depressions extends across the isthmus from the great coast lagoon in the north to the Gulf of Suez, and affords the route for the Suez Canal (q.v.).

**SUEZ CANAL.** A canal about 100 miles in length, which crosses the Isthmus of Suez and connects Port Said on the Mediterranean Sea with Port Thewfik on the Red Sea. In 1854 Ferdinand de Lesseps (q.v.) obtained permission from Said Pasha to form a company to construct a waterway from sea to sea without locks, and in 1855 an "International Consultative Commission" selected from among the most celebrated civil engineers of Europe was appointed to report upon the scheme. The final report of this commission was submitted to and accepted by the Viceroy in June, 1856. Its conclusions were in effect as follows: A direct route through the isthmus from Suez to the Mediterranean was adopted. The dimensions of the channel were to be as follows: from the Red Sea to the Bitter lakes, depth 26¼ feet, bottom width 210 feet, top width 320 feet; from the Bitter lakes to the Mediterranean Sea, depth 26¼ feet, bottom width 144 feet, top width 262 feet. At Port Said the plan of extending jetties directly seaward to protect the entrance was adopted. (See JERRY.) Basing his efforts on these conclusions, M. de Lesseps succeeded, in 1858, in forming a company, with a capital stock of £8,000,000, to build the canal.

**Topography.** The construction of the canal was greatly facilitated by the existence along the route of four dried-up depressions which were formerly and have again become lakes of considerable area, viz., the two Bullah lakes, the Great and Small Bitter lakes, and Lake Timsah. (See Map of Egypt.) These low-lying basins have an aggregate length of 27 miles. Excavation was required, however, through the Bullah lakes, Lake Timsah, and the Small Bitter Lake, and also through a portion of the

Great Bitter Lake. Consequently it was only for a length of 8 miles of the Great Bitter Lake, where the natural depth exceeded that of the canal, that no excavation was necessary. The total distance from Port Said to Suez, Port Thewfik, is 88 nautical miles, or about 100 English miles. The only serious obstacles to be overcome in the line of the canal were at El Gisir, the summit of the work, situated between the Bullah lakes and Lake Timsah, where the hills crossing the canal vary from 30 to 60 feet above sea level over a length of 6 miles, and at the deep cutting of Serapeum, between Lake Timsah and the Great Bitter Lake. From Port Said to Kantara, a distance of 24 miles; the canal passes through Lake Manzaleh, a shallow lagoon which covers an area of nearly 1000 square miles. The soil encountered along the route was sand, sandy clay, and hard clay, with rare stretches of rock, and thus favorable to rapid and easy excavation. No serious engineering difficulties were presented by the harbor works at Port Said and Suez, and unlike the Panama Canal no locks were required. In short, the canal works in general were of a very simple nature, but of vast magnitude, involving, as originally proposed, the removal of 60,000,000 cubic meters of dry earth and 56,000,000 cubic meters of earth under water; and as they were situated in a country destitute of fresh water, a well-conceived organization was required to bring the colossal work to a successful issue.

**Progress of the Work.** Work on the canal was begun on April 25, 1859. The work progressed slowly at first, but the installation of a large fleet of dredges by means of which the dredged material carried by long and high projecting chutes was rapidly delivered on either bank of the canal at some distance from the slopes of the cuttings without the intervention of barges, and other mechanical appliances, had the effect of reducing by three-fourths the number of workmen needed to open the canal by the time originally estimated. More important than these, however, was the completion, in 1863, of a fresh-water canal and pipe line from Cairo by the way of Ismailia to Port Said. Financial difficulties were overcome, first, by decreasing the width of the bottom of the canal to 72 feet and the depth to 26 feet, 2 inches, its dimensions when opened, and, second, by virtually increasing the capital of the company to £17,100,000. To compensate for the greatly reduced width of the canal, sidings were provided at every 5 or 6 miles between Port Said and Lake Timsah to allow vessels to bring up either for the purpose of passing each other or to moor for the night. In April, 1867, water from the Mediterranean was let into the marshy bed of Lake Timsah, and in March, 1869, it was allowed to flow into a near-by dry salt-incrusted basin of the Bitter lakes. After five days of great pomp and ceremony (Nov. 16-20, 1869) the canal was opened to traffic and was available for ships drawing not more than 24.4 feet. The canal had cost up to Dec. 31, 1869, £16,632,953.

**Enlargement of the Canal.** In 1883 it became evident that, owing to the great increase of traffic, a radical plan of improvement was demanded. In 1884, therefore, a second International Consultative Commission was appointed to consider the whole question and to report plans. This commission made its report in 1885, and shortly thereafter the enlargement works were begun according to the general plan

recommended by the commission. In 1890 ships drawing 25.4 feet were allowed. Another enlargement was completed in 1898; it consisted in an increase of the bottom width of the canal to 121½ feet, and an increase of the navigable depth to 27 feet, 10 inches. The increase in depth was at the rate of about one foot every six years, so that on Jan. 21, 1915, the maximum draft permitted was 30 feet. In addition to this uniform enlargement of section there were completed in 1899 nine new sidings, each 49 feet wide and 2460 feet long. A depth of 40 feet throughout the canal was being aimed at, and the company had power to raise bonds up to \$30,000,000 for the work, which would have been completed by 1919 had it not been for the war. Although Sydney, Australia, was the only Australasian port with a depth of harbor greater than that of the Suez Canal, yet the depth of the Panama Canal, 40 feet, and that of many Atlantic ports, made such increased depth desirable. In 1914 the average time of passage was 16 hours and 11 minutes for vessels navigating by night as well as day. The maximum speed permitted was 5½ nautical miles per hour.

**Night Navigation.** In 1885 it was decided to make use of electric light in such a manner as to insure a safe passage by night through the canal, the company hoping in this way to diminish the traffic by day and thus to render the navigation less difficult until the full enlargement of the waterway was accomplished. A vessel passing by night carries four lights, one astern, one on each side, and a strong searchlight ahead capable of sending light 4000 feet ahead of the vessel. The effect of this system of lighting so as to permit night navigation virtually doubles the carrying capacity of the canal.

**Traffic and Revenue.** The toll charged for the passage of the canal was 10 francs per ton and 10 francs per passenger when the canal was first opened. From time to time there have been discussions as to the transit dues, and recent reductions in charges have led to smaller revenues. From the time of opening various changes were made in succeeding years, and in 1903 the toll was 8½ francs per net ton for loaded vessels, 7 francs for empty ships, and 10 francs per passenger. On Jan. 1, 1913, a reduction to 6¼ francs per ton was made. The reduction of toll rates naturally affected the receipts. The accompanying table shows the traffic of the canal from 1869 to 1914, inclusive:

YEAR	Vessels	Gross tonnage	Net tonnage	Transit receipts
<i>- Francs</i>				
1869.....	10	10,558	6,576	54,460
1870.....	456	654,915	436,609	5,159,327
1875.....	1,494	2,940,708	2,009,984	28,886,302
1880.....	2,026	4,344,520	3,057,422	39,840,484
1885.....	3,624	8,985,412	6,335,753	62,207,439
1890.....	3,389	9,749,129	6,890,094	66,984,000
1900.....	3,441	13,699,238	9,738,157	90,623,608
1905.....	4,116	18,310,442	13,134,105	113,866,796
1910.....	4,533	23,054,901	16,584,898	130,436,547
1911.....	4,969	25,417,853	18,324,794	134,762,199
1912.....	5,373	28,008,945	20,275,120	136,423,831
1913.....	5,085	27,737,180	20,033,884	126,650,934
1914.....	4,802	26,866,340	19,409,495	122,248,853

In 1914 Great Britain led in the number of vessels passing through the canal with 3078 of 17,756,322 gross tons and 12,910,278 net

tons. Germany was second with 481 of 2,961,755 gross tons and 2,118,946 net tons, and was followed by Holland with 347 vessels, 1,925,036 gross tons, 1,389,390 net tons, and France with 228 vessels of 1,217,406 gross tons and 799,624 net tons. Flying the United States flag were 3 vessels of 5264 gross tons and 2562 net tons.

During the first six months of 1915, 1750 ships passed through the Suez Canal, paying tolls to the amount of about \$8,750,000, as compared with 2571 ships for the corresponding six months of 1914, or previous to the outbreak of the Great War. In these six months the amount of toll paid was approximately \$13,000,000. Deducting the number of German, Austrian, and Turkish ships which naturally were unable to use the canal in 1915, it would appear that the amount of traffic and receipts therefrom was little below the ordinary.

**History.** The plan of a water connection between the Mediterranean and the Red Sea goes back to early Egyptian history. Such a canal seems to have been constructed in the reigns of Seti I and Rameses II (about 1350-1300 B.C.), extending from the Nile to Lake Timsah and thence to the Red Sea. When this had been choked up by the sands in the course of ages, a new canal was begun by Necho, a son of Psammetichus I (about 600 B.C.), between Bubastis on the Nile and the Red Sea, but was left unfinished till the time of Darius Hystaspis (521-486 B.C.), who completed the work. About the beginning of the Christian era the canal was no longer navigable, but it was probably restored under Trajan. The last restoration was made in the seventh century by Amru, the Mohammedan conqueror of Egypt, who connected Cairo with the Red Sea. During Napoleon's invasion of Egypt (1798-99) the project of piercing the isthmus was carried to the extent of preliminary surveys being made, but, owing to a miscalculation on the part of the engineers which seemed greatly to enhance the difficulties of the work, the execution of the plan was delayed till the French were forced to abandon Egypt. An international commission of engineers made a preliminary survey in 1846 to ascertain the practicability of a level-water canal. The English engineer on the commission, George Stephenson, strongly opposed a canal and recommended to his government a railroad from Cairo to Suez, and this was constructed by British capital in 1858. By the terms of the De Lesseps concession (see above) the canal was to be constructed without expense to Egypt, which was to receive 15 per cent of the gross receipts for 99 years, at the expiration of which period the canal was to revert to the Egyptian government. When, however, De Lesseps found it impossible to enlist the large amount of capital necessary, he turned to Said Pasha, secured from him a large loan for preliminary work and promoting, and later a subscription for nearly half of the stock, which was about £17,000,000. Said was not able to pay his subscription and his warrants had to be cashed in London. The Egyptian government had agreed to furnish labor at a nominal price, the fellaheen to be well treated and their health to be cared for. The violation of the latter condition on the part of the canal company aroused a protest in the name of humanity, especially from England, which had never looked with favor on the canal and suggested to the Sultan that the work be stopped. His approval of the concession, as suzerain,

which had been provided for in the original contract with Egypt, had never been obtained. He now approved the concession, but decided that the fellaheen must not be forced to do the work. The company complained of the Egyptian government's compliance with this order from Constantinople as a breach of contract, made heavy claims for damages, induced the Khedive to accept Napoleon III as arbitrator, and on this and a later claim wrung from the exhausted resources of Egypt over 80,000,000 francs. The direct and indirect cost of the canal to Egypt is estimated at about \$85,000,000. In 1875 Ismail Pasha (q.v.) appealed to Europe for aid in his financial difficulties. Among other measures that were taken was the sale of his canal stock to England, 176,602 shares, for £4,000,000 effected through the foresight of Lord Beaconsfield, who outwitted a French syndicate by asking the Khedive outright if the shares were for sale. (See DISRAELI.) This made England, which had originally opposed the canal project, the heaviest owner in it, and combined with the general financial assistance rendered to Egypt gave that power a direct interest in Egyptian affairs. A very short time sufficed to show that the canal was of the utmost value as the passageway between England and her Oriental possessions. Under the control of British and French capitalists the commercial development of the canal followed unchecked until the Great War. There was no preferential treatment in its use, and ships of all nations employed it on equal terms.

England and France at first exercised together that tutelage over Egypt which the financial situation rendered necessary. Later events led England to assume this responsibility alone. The Suez Canal was the key to this political development, as it became in part to the complicated situation in the Near East previous to and during the Great War of 1914. In fact its protection against Teutonic and Turkish attacks was an important consideration that bulked large in the strategy of the war and for that reason it was well guarded by British troops. Rumors of the closing of the canal in 1915 severely affected freight rates and commerce. See EASTERN QUESTION; EGYPT; WAR IN EUROPE.

R. Johnson, *Panama Canal Traffic and Tolls* (Washington, 1912), including notes on finance, traffic, etc., of the Suez Canal.

**SUFFERN.** A village in Rockland Co., N. Y., 32 miles north by west of New York City, on the Ramapo River and on the Erie Railroad (Map: New York, Insert, A 1). It has the convent of the Holy Child and a fine high-school building. There are ironworks, a foundry, per-

**SUFFRAGAN** (ML *suffragari*, to assist, to vo

given to a bishop to express his relation in a province to the archbishop or metropolitan (q.v.). The name is also applied to coadjutor or assistant bishops, especially in the Church of England. The Protestant Episcopal church in the United States provided in 1910 for suffragan bishops, without right of succession, but eligible to election as bishops or bishop coadjutors. In the Roman Catholic church similar assistant bishops are usually designated by the titles of extinct sees. See **TITULAR BISHOPS**.

**SUFFRAGE** (Lat. *suffragium*, vote). In a representative government, the act of a qualified voter in participating in the choice of government officials or in voting on laws or constitutions submitted to the electorate. There are two views as to the basis of suffrage. One holds that it is a privilege bestowed by the state upon such citizens as are capable of exercising it intelligently and for the public welfare. The other view regards it as the natural right of all adult citizens. By most states suffrage has been restricted to some of the following bases: sex, ownership of property, payment of taxes, educational attainments, moral character, residence, religious profession, etc. An almost universal rule has been to exclude children, lunatics, idiots, convicted criminals, and aliens from the exercise of the suffrage, although there are still exceptions.

In the American Colonies qualifications for suffrage varied greatly. In Virginia the suffrage was restricted to "freeholders and housekeepers," in Massachusetts until 1664 it was restricted to church members; in the New Haven Colony it was the same; under the Massachusetts charter of 1692 it was restricted to freeholders of a certain amount of property. The religious tests were first to be abolished, the last survival of the kind existing in South Carolina from 1778 to 1790. The right of each State to regulate the suffrage within its limits was recognized by the Federal Constitution, and in hardly any two States were the requirements the same. During the early part of the nineteenth century a freeholder qualification was required in Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Virginia, Maryland, North Carolina, and South Carolina, the amount ranging from £20 in New York to £60 in Massachusetts or from 25 acres of improved land in Virginia to 50 acres in Maryland and South Carolina. The payment of taxes alone was required in Pennsylvania, Delaware, and Georgia. Early in the nineteenth century the freehold requirement was abolished in nearly every State. The tax and ownership of personalty qualifications disappeared in most States, so that adult male suffrage became the general rule long before the outbreak of the Civil War. Free negroes were almost everywhere excluded.

A readjustment of the suffrage followed the Civil War. The Reconstruction Acts of 1867 conferred the right of suffrage on the freedmen. In the States that had rebelled the negroes voted for the first time in 1867, in the elections for delegates to the reconstruction constitutional conventions, and in the following year on the question of adopting or rejecting the new constitutions. The States having once been readmitted to the Union, however, there was nothing to prevent them from withdrawing the right temporarily bestowed on the freedmen by Congress. The Fourteenth Amendment was in-

tended to guard against such action on the part of the reconstructed States. On account of the difficulty of enforcing this amendment and the inadequacy of protection which it afforded the negro population, the reconstructionists advanced another step. In the first place, it was made a condition precedent to the readmission to the Union of the remaining unreconstructed States that they adopt constitutions with unamendable provisions guaranteeing the right of suffrage to negroes. At the same time the Fifteenth Amendment to the Federal Constitution was carried. But the Constitution confers the right of suffrage directly on no one, so that there are no United States voters. This is a prerogative of the individual States, and they may exclude any number of persons on other grounds than race or color, such as illiteracy, lack of citizenship, nonpayment of taxes, etc., subject to the penalty of a reduction of representation in Congress.

**Grandfather Clause.** In the effort of the Southern States to restrict the negro vote many of them had enacted so-called "grandfather clauses." The usual method was to limit the right to vote by some educational or property qualification, but to exempt from such qualification those who could vote prior to 1866 and their descendants. Such clauses were declared null and void by the United States Supreme Court in June, 1915, in two cases based on the Oklahoma constitution and the Maryland statute. All such clauses were declared by the court to be subterfuges designed to defeat the express intent of the Fifteenth Amendment. Moreover the court upheld the criminal conviction of Oklahoma officials and the fining of Maryland officials for refusing suffrage privileges to negroes.

The attainment of the twenty-first year of age is a qualification in every State. To the beginning of 1916 the States of Wyoming, Colorado, Utah, Idaho, Washington, California, Arizona, Kansas, Oregon, Nevada, and Montana, and the Territory of Alaska had granted women equal suffrage rights with man; in Illinois women had gained the right of voting in the filling of all offices not created by the State constitution; 19 States had granted to women the right of suffrage in school elections, and Iowa in municipal elections on proposals to vote bonds or increase tax levies. The States may and generally do require voters to register within certain periods as a means of preventing frauds at the election, and this requirement indirectly excludes some. Residence within the State and district for a certain period previous to the election is an almost universal requirement. Educational tests have long existed in Massachusetts and Connecticut and have been introduced in a number of Southern States, as a result of which the suffrage has been practically restricted to the whites in Mississippi, South Carolina, Louisiana, North Carolina, Alabama, and Virginia. See the sections on government of the various countries and States for suffrage requirements. See **WOMAN SUFFRAGE**.

chase in the Thirteen English Colonies in America (Philadelphia, 1905); A. C. Ludington, *American Ballot Laws, 1888-1910* (Albany, 1911); McLaughlin and Hart (eds.), *Cyclopedia of American Government*, vol. iii (New York, 1914).

**SUFFREN DE SAINT-TROPÈZ**, su'frän' de sän'trô'péz', PIERRE ANDRÉ DE (1726-88). A French naval hero, born at Saint-Cannat, near Lambesc. He was captured by Hawke in 1747 and after his exchange served for several years in the vessels of the Knights Hospitalers of Malta (q.v.). He was again with the French navy in the Seven Years' War, in 1767 returned to the service of the Knights of Malta, and in 1772 was commissioned as a captain in the French navy. In 1778-79 he served with distinction in the squadron of D'Estaing (q.v.) which operated on the American coast and in the West Indies. In 1781 he was given command of a squadron of five ships, sent out against a British fleet under Commodore George Johnstone. He found Johnstone's fleet in Porto Praya, Cape Verde Islands, and inflicted so much damage that the British expedition failed in its purpose of conquering the Dutch South African settlements. He then proceeded to the East Indies, where his four principal actions against the superior forces of the British Admiral Sir Edward Hughes, taken together, were the most brilliant operations ever performed by a French naval commander. The strategic results of his campaign were most important, and if proper use of them had been made by the French land forces, the British hold upon India would have been seriously menaced. Suffren was made a vice admiral; he had long been known as the Baillie de Suffren from a high office he held in the Knights of Malta.

**SUFISM**, soo'fe-iz'm (from Ar. *sūfi*, clad in woolen, from *sūf*, wool). A system of Mohammedan mysticism, having its home chiefly in Persia.

Mohammedanism is not a mystical religion, but it contained from the first elements which could be used by mystics. Not till its second century did mysticism become organized in it. The word "Sufism" seems to have been first adopted by Abu Hashim, a Syrian (A.D. 780), who founded a mystic community at Ramleh in Palestine. Abul Saïd Abul Khair (about 820) is mentioned as founder, while Al-Ushairi (1073) states that the name was in common use about 815. Mythical tales give the origin to Rabia al Adawiyya (752), a pious woman much spoken of in Sufism. There seems to be historic evidence to prove the Sufi claim that, in spite of Mohammed's precautions against mysticism, his favorite Ali was not free from its influence. Sufism is radically theistic and is led by its theism to consider God as absorbing the universe. The Vedanta is pantheistic with occasional theistic phraseology. The Sufis are so strongly devoted to the Beloved (viz., God) that they look for Divinity everywhere and see Divinity anywhere. It became easy, even for the Persians, to interpret this in a pantheistic way. The intellectual forms given to most of the Sufi doctrines in Persia are from foreign sources, among which must be mentioned Buddhism, the Peripatetic philosophy, and Neo-Platonism.

A few really great Sufis lived before the close of the second century of the Hejira (815). Among them and those immediately after are

to be mentioned the Egyptian Dhun-Nun (859), who introduced the doctrine of ecstasy and mystical stages; Sirri Sagvati (867), who introduced unification; Junaid (910), who reduced Sufism to writing; and Al-Nallaj, who became famous because he went about crying "I am the true One," for which he was put to death by torture (921). The *Fihrist* (987) represents him as a "wily conjurer," but Sufis consider his death the result of the workings of the occult law which brings death upon him who divulges divine secrets. Ghazali (q.v.) (died 1111) and Jalal ud din Rumi (q.v.) (died 1273) were the two most famous doctors in Sufism. The most brilliant Persian poetry is Sufi. Aside from Rumi, the Sufi poets are Nizami (q.v.), Farid ud din Attar (q.v.), Sadi (q.v.), Shamsi, Hafiz (q.v.), Anvari, Jami (q.v.), and Hatifi (q.v.). It may be added that Omar Khayyam (died 1123), known to the West through Fitzgerald's translations, is not a Sufi. Jami (died 1492) has been called the last Sufi, and with some justice. After him Sufism slowly declined, but the nineteenth century saw its powerful revival in Turkey, though its Turkish representative names are almost unknown outside of Turkey. From Turkey and Egypt comes what may be called a Neo-Sufism.

Primitive Sufism is not doctrinal; it is an "experience," a "feeling of God," a "mystery of godliness," and does not primarily have anything to do with the notions of the intellect. Within 200 years from its origin, however, it assumed doctrinal forms. The two chief doctrines of Sufism are that of the One (*Aḥad*) and that of "the Way to the One" (*ṭariqat*). A Sufi first of all endeavors to realize that "the One" is the only existence, that there is not only "no god but God," but that there is nothing but God. Next, he enters upon "the journey to the rose garden of Union." The Sufi's belief is not pantheism in the Greek sense; he does not "make everything God except God himself"; on the contrary, everything is naught except Divinity and it is Divinity that gives life to the dead Nonbeing. The world is a phantasmagoria, and the time will come when it shall pass away. God's reason for creating the world is found in this saying: "I was a Hidden Treasure and I wished to be known, so I created Creation that I might be known." The form of creation is not only truth and goodness, but also and essentially beauty. Sufis lay more stress upon the conception of Divinity as beauty than other mystics or religions.

The Sufi "way to God" is similar to the well-known ideas on that subject among Western mystics. With the help of a guide, "the traveler" ascends step by step to union with God or through awakening to regeneration and sanctification to union. The "Way" is ascetic and full of occult practices, such as dances, silences, etc., and leads to the mystic trance of perfect union with God, when man loses all sense of independent individuality. All men may reach union.

Sufi symbolism permeates the entire system of Sufism. A symbol to a Sufi is not merely an object which stands for some other object or idea. For him every object has besides its own immediate signification also an ideal content, and it is this latter which is the real object of the Sufi's search. He finds it by means of love (*isq*). Objects are therefore veils, not veils that hide, but veils that reveal the One.

All Sufi poetry is written with a double sense and the initiates can read five other senses besides. The now comparatively well-known ghazels of Hafiz, Sadi, Jami, and others abound in veils, which the Occidental calls voluptuous and bacchanalian, but to the Sufi they are descriptive of emotions or soul life. As such they suggest to him deeper and more universal states of life.

There are many sects among the Sufis, but their differences are not strictly Sufistic; they have arisen on external and unessential ground and are of little interest outside of Sufism. Sufism has exerted a powerful influence in Arabia, Persia, and Egypt, and it is flourishing to-day in Turkey. India also has a large number of Sufis. Persian literature, more than any other, bears strong impress of it.

**SUGAR, MANUFACTURE OF.** Cane sugar is found in varying quantities in many plants, but sugar cane (*Saccharum officinarum*), the sugar beet (*Beta vulgaris*), the sugar maple (*Acer saccharinum*), and various species of palms are its only commercially important sources. At one time the United States Department of Agriculture and several of the States experimented with sorghum (*Sorghum vulgare*), which seemed a promising source of cane sugar, but though several varieties containing from 10 to 20 per cent of cane sugar were produced by seed selection, sorghum has not been found a favorable plant for sugar manufacture because of the great difficulty in purifying the juice. Several sorghum sugar factories were erected in Kansas and elsewhere about 1890, but development failed to pass the experimental stage. The plants are, however, used quite extensively for making sirup. (See **SORGHUM**.) Owing to the presence of impurities, including saccharine substances other than cane sugar, raw sugars obtained from various plants differ

greatly in flavor, but, contrary to popular belief, the granulated or refined sugar derived from them differs not at all in sweetening power, since it consists of more than 99 per cent of sucrose and less than 1 per cent of impurities including mineral matter, water, etc. The world's sugar supply is about equally divided between cane and beet. Practically all of the European consumption is beet sugar produced chiefly in Germany, Austria, Russia, and France. The chief cane-sugar-producing areas are Cuba, Java, Hawaii, Porto Rico, the Philippines, and India.

**Cane Sugar.** Sugar cane (q.v.) is the oldest sugar-producing plant. During the middle of the eighteenth century it was introduced from southern Europe into Louisiana, where the successful manufacture of sugar began during the last decade of that century. Until it had to compete with beet sugar manufactured under the most scientific conditions, raw sugar was generally produced from the cane by very crude methods. The proportion of the juice of the cane extracted by pressure was comparatively small, and was subjected to little purification before being evaporated in open pans (kettles), and the molasses allowed to drain off.

The modern sugar factory is a highly efficient plant operated in accordance with the most advanced findings of science. The juice of the cane is extracted in mills consisting mainly of a system of rollers, often nine or twelve in number, arranged in sets of three, through which the cane successively passes. The process is called grinding. The cane delivered by carriers first passes through two huge corrugated rollers, which break and prepare it for the heavier pressures applied by the succeeding sets of three rolls each. The hydraulic pressure upon the rollers is increased at each successive set to remove more and more of the juice. Between the sets of rollers the crushed cane is sprayed with water, or macerated, to facilitate the removal of sugar. This process removes from 90 to 95 per cent of the sugar, according to the efficiency of the apparatus and the care with which it is operated. The crushed cane, called bagasse, is used for fuel to furnish steam for the engines and pumps, and for the evaporation of the juice.

Lime is added to the raw juice drawn from the mill, which is then heated to boiling, and the insoluble compounds of lime formed with the organic and phosphoric acids, the albuminous bodies and other impurities, rise to the surface and are removed by skimming and by allowing the juice to settle. Often the juice is passed through filter presses. In some factories it is treated with gaseous sulphur dioxide to bleach it and to aid in removing the impurities. The next step is evaporation. Under primitive conditions this was done over a fire in open pans or kettles. Caramelization is unavoidable by the open-kettle method, and the sugar is characterized by a dark color and aromatic taste. In some countries, as the Philippines, the juice is evaporated to a thick mass and allowed to solidify, this being known as concrete sugar. In some South American countries the evaporated mass is run into hogsheds having a finely perforated bottom, allowing the molasses to drain off. The residue is sold as muscovado sugar.

In the modern sugar factory evaporation is carried on under vacuum, to avoid loss of sugar.

Vacuum evaporators are arranged usually in series of two, three, four, or even more. In the first vessel of a series a lower vacuum is maintained than in the second, and so on, the temperature of boiling for each succeeding vessel being thus reduced. Steam is applied to the first pan and the vapor from the boiling juice is used to heat the second pan, and so on. The juice passes continuously through the pans, from the last of which it issues as a sirup.

The sirup is then admitted to the strike pan, a cylindrical cast-iron vessel provided with a vacuum pump, condenser, and a set of copper coils, to which steam may be admitted as desired. After further condensation, and when one-fourth to one-third full of thick liquor, the sugar will begin to crystallize in small grains. When enough of these have appeared so that it is known from experience that they will have grown to a desired size by the time the pan is full, more sirup is drawn in, thinning the contents to such an extent that the formation of new crystals will be stopped. In like manner more sirup is gradually added, its contained sugar attaching itself to the crystals already formed. Care is necessary that the mass be at no time thickened to such an extent that new crystals, false grain, are formed, as these will cause great trouble in the after working. The handling of the vacuum pan requires more skill than any other operation in the sugar house. The process is controlled by drawing out samples from time to time, which are tested upon glass to see the consistency and size of the crystals. When the vacuum pan is filled with crystallized sugar the pan is emptied, the dense mass of sugar crystals and sirup, massecuite, being conveyed to cylindrical metal vessels (centrifugal machines) with perforated walls and supported upon vertical shafts making from 1000 to 1500 revolutions per minute, the force throwing the sirup out through the walls. After spraying with water to further remove the molasses, the raw sugar is removed and packed.

This is known as first sugar and the molasses as first molasses. The latter contains a large amount of sucrose, for the recovery of which there are various processes. The first molasses is sometimes boiled down again in the vacuum pan and a second crystallization, called the second sugar, is now obtained. This may be repeated until a third sugar is obtained. The tendency in modern methods, however, is against repeated boiling of the molasses. The aim is to get as much sugar as possible from one operation. One method is to draw the molasses from the first strike of sugar into the pan with the sirup for the succeeding strike and boil the two down together. The massecuite from the mixture is drawn while hot into large tanks, where it is kept in slow motion by revolving arms until all the sugar is crystallized out that can be recovered.

Latterly the manufacture of white sugar directly from the juice without resorting to a refining process has greatly increased. This is accomplished by various modifications in the details of manufacture, especially in the clarification process and the rapid handling of the juice.

**Beet Sugar.** The manufacture of sugar from beet roots is a comparatively modern industry, having its inception in the investigations of Margraff, who in 1747 announced to the Berlin Academy of Sciences the analysis of several

sugar-containing plants, and predicted that the sugar beet (q.v.), being the most saccharine of the plants examined, would become the basis of a great industry. Nearly half a century later the problem was solved by a pupil of Margraff, Achard, who made a considerable quantity of beet sugar and announced his methods to the Berlin Academy of Sciences and to the Institute of France in 1797 and 1799, respectively. In Germany several beet-sugar factories were built within the next decade, and beginning with 1810 the industry, being stimulated by governmental aid in both countries, developed steadily.

In the manufacture of beet sugar the beets, delivered from the storage sheds by water power after being thoroughly washed, are cut into thin slices or chips and conveyed to a diffusion battery, consisting of a series of tall boiler-shaped cylinders called cells. A series of 12 to 14 of these cells constitute a diffusion battery, so called because the sugar is removed from the chips by water at about 85° C. into which the sugar diffuses, and which passes through all the charged cells of the series. Heaters are placed between the cells to maintain the temperature. The exhausted chips are pressed, dried by the heat from the flue gases, and used as stock feed.

The diffusion juice, containing from 12 to 15 per cent of sugar, is treated with a considerable excess of lime to purify it, and the dissolved lime is precipitated by carbon dioxide, together with certain impurities, after the removal of which the operations of liming, carbonization, and filtering are repeated. The juice is then evaporated, crystallized, and centrifuged, as in making sugar from cane juice. The raw beet sugar is not suitable for food until it is refined. Many processes have been devised for recovering the sugar in the low-grade beet molasses, in one of which, the Steffens, it is diluted and treated with very finely powdered lime, the insoluble trisaccharate of lime formed being removed by filter presses. It is then added to the diffusion juice, the carbonation liberating the sucrose. In 1914 there were 60 beet-sugar factories in the United States as compared with 32 in 1900. These 60 factories were located as follows: California 10, Colorado 13, Idaho 4, Michigan 15, Ohio 3, Utah 7, and other States 8. The development of the beet-sugar industry in the United States in recent years indicates that the entire sugar requirements of the country could be thus supplied. The production grew from 5,000,000 pounds in 1890 to 163,000,000 in 1900 and 1,500,000,000 pounds in 1915.

**Maple Sugar.** The manufacture of maple sugar is carried on more or less wherever sugar-maple trees are abundant, especially in the northern Atlantic and northern Central States, the leading producers, according to census returns, being Vermont and New York. The total production in the United States as given by the thirteenth census was 14,000,000 pounds of maple sugar and 4,106,418 gallons of maple sirup. In some cases the natural groves have been extended by planting. The busy period depends upon the locality and the season, sometimes beginning in February, sometimes lasting until the middle of May, the best flow of sap coming with daily alternation of thawing and slight freezing. See MAPLE.

The most popular modern method of tapping the trees is to bore a half-inch hole not more than 1½ inches into the tree near the ground

and to drive in a metal or wooden spile. This conducts the sap and also serves to support the bucket, from which the sap is collected each day and boiled as soon as possible, to avoid deterioration. All sorts of apparatus, including culinary utensils, are used for boiling the sap; the most approved is a steam-heated evaporator, of which there are several makes. In these the sap flows through a winding channel, emerging as the finished product, which, owing to its freedom from molasses, quickly solidifies if evaporated.

The sap contains about 3 per cent of sugar, but occasionally exceeds 6 per cent; and at this average a yield of three pounds a year is considered profitable. Large trees and trees with rich sap often yield more. Impurities rarely exceed 5 per cent. There is, however, a small amount of insoluble material removed by skimming. Reliance is placed on quick boiling and skimming without clarifier to produce a light-colored and otherwise satisfactory sugar. The only impurity that causes trouble is the so-called sugar sand, composed mainly of acid malate of lime, which collects on the bottom of the pans, interferes with the boiling, and makes the sirup cloudy and the sugar gritty.

**Palm-Tree Sugar.** The jaggery, made principally in the East Indies from various species of palms (Phoenix, Borassus, Cocos, and other genera), is a dark-colored raw sugar made in a crude way by methods not essentially different from those described, except that a little lime is added as a clarifying agent. It plays a minor part in the world's markets.

**Sugar Refining.** The process usually consists in dissolving the raw sugar in water, filtering through cloth to remove suspended matter, decolorizing by filtration through bone black (bone charcoal), and granulating in a vacuum pan as above described. By modern methods the raw sugar is liquefied with sirup, which is then removed with centrifugal machines, taking a large part of the liquor originally adhering to the sugar crystals with it, and forming a sirup which can be used for further liquefaction. The sirup not required for this follows the dissolved sugar through the various processes, and is boiled in on top of the white strikes. The centrifugal sirups, when too poor to be returned to the white pans, are boiled alone, the product being sold as soft sugar or remelted. Boiling to grain before placing in crystallizers or tanks is generally practiced. If such additions are not made, and the entire strike is boiled from washed and thoroughly cured raw sugar, bluing is rarely required.

**Statistics.** The total production of cane sugar in 1914-15 was 9,956,523 long tons, of which the United States and its dependencies produced 1,343,196 (exclusive of that produced and consumed in the Philippine Islands). The production of beet sugar amounted to 8,288,499 long tons, divided as follows: Europe, 7,629,740; United States, 646,257; Canada 12,502. The per capita consumption (1910) ranged from 86.3 pounds for England (United States 81.6) to 14.2 for Spain.

**Molasses.** Molasses is an uncrystallizable liquid which seeps from the massecuite or is thrown out by the centrifugal machine. These seepings may be reboiled if they contain considerable sugar, but are quite valuable as molasses owing to their flavor and sweetness. Since the introduction of the vacuum pan and

centrifugal machine molasses has become less plentiful, the small quantities made being used where cane sugar is manufactured. No table molasses is made from the sugar beet, because the impurities cannot be removed by any known process. Normally, cane molasses made by the open-kettle process contains about 30 per cent cane sugar, 23 per cent reducing sugar, and 47 per cent water, ash, and impurities; that made in a large modern factory, 20 per cent cane sugar, 25 per cent reducing sugar, and 51 per cent water, etc. Beet molasses contains 47 per cent cane sugar, 5 per cent reducing sugar, 20 per cent water, 22 per cent organic matter other than sugars, and 6 per cent ash, etc. In sugar-manufacturing regions molasses is mixed with such bulky materials as cottonseed meal, dried beet pulp, etc., to be easily handled and fed to stock as a cheap source of carbohydrate food.

**Milk Sugar or Lactose.** Sugar of milk, occurring only in the milk of mammals, is found to the extent of 4 or 5 per cent in the milk of herbivorous animals. It is obtained by first curdling the milk with rennet or other agent to remove the casein and the fat, and then drawing off and evaporating the clear whey to a sirup in which, when cold and still, the milk sugar crystallizes and sinks. The deposit is recrystallized after being dissolved in hot water, sometimes as hard cylindrical masses on strings. See MILK; FOOD.

**Food Value of Sugar.** Since milk sugar and dextrose are used for human food to a far less extent than cane sugar, which they resemble somewhat closely in action, the statements in the following paragraphs are confined to cane sugar. In its food value sugar resembles starch, being considered a fat former and a source of energy with a fuel value of 1860 calories a pound. Thus it is ranked as a more readily available heat producer and force conserving than starch (q.v.). The wholesomeness and utilization of sweetened foods is largely a matter of quantity or concentration, a simple dish flavored with sugar being considered easy to digest, but a heavily sweetened one eaten singly, more or less difficult because of its concentration.

**SUGAR BEET** (*Beta vulgaris*). A field crop of the natural order Chenopodiaceæ, botanically the same species as the garden beet, important commercially as the source of about one-half of the world's supply of sugar. (See SUGAR, Beet Sugar.) The sugar beet flourishes upon a rich, deep, loamy soil in a climate having a mean temperature of about 70° during the growing season. The seed is planted and the crop cultivated and harvested generally by means of implements and machinery. The rotation of the crop with others is carefully planned and the proper fertilization of the fields has been a subject of much study. In commercial beet-seed production beets with about 15 per cent of sugar are selected, placed in pits during the winter and set out again in the spring to produce the seed crop. This is necessary as the plant is a biennial, and in the regions where most of the seed is produced in France, Germany, and Austria-Hungary, the winters are sufficiently severe to injure the beet if simply left in the ground. Some beet seed is produced in the United States, but the practice is hardly beyond the experimental stage. (See SUGAR.) The average cost of growing an acre of sugar beets in the United States is estimated at about \$30. The average yield in the best districts is about 12 tons, with an average sugar content of 14.5 per cent. This represents a yield of about 3900 pounds of sugar per acre, though yields up to 4800 pounds have been reported. In some cases the percentage of sugar in the beet runs up to 18 or even 20 per cent. Consult: Department of Agriculture, Bureau of Chemistry, *Bulletin No. 27* (Washington, 1890); H. Briem, *Der praktische Rübenbau* (Vienna, 1895); Barnett, *References to Literature of Sugar Beet* (Washington, 1897); also bibliography under SUGAR.

**SUGAR-BEET DISEASES.** The sugar beet is subject to the same diseases as the common beet (q.v.), but a few diseases are espe-

cially troublesome on account of the reduction in stand and the lowering of the sugar content due to their attack. The seedlings may be destroyed by a number of damping off fungi. In Europe the crown rot (*Phoma betæ*) is probably the most destructive disease of the sugar beet, while in the United States crown gall and curly leaf cause most injury to the growing crop. Two forms of crown gall are recognized, both of them due to bacteria (*Bacterium tumefaciens* and *Bacterium beticola*). Both reduce the sugar content of the beets and may be followed by various rots, otherwise they do not reduce the tonnage of the crop. The curly top, which is characterized by dwarfed and curled foliage, reduces both the yield and sugar content. This disease is especially severe in the western beet fields. There seems to be some relation between the presence of leaf hoppers as carriers and the occurrence of curly top but the connection has not yet been fully worked out.

**SUGAR-BEET GUM.** See GUMS.

**SUGAR-BEET INSECTS.** The recent introduction and rapid spread of the sugar beet have resulted in the attacks of several insects not before known as injurious and have given a new food to others. A leaf miner (*Pegomya ricina*), 30 or 40 larvae of which may be found in a single leaf, has produced serious damage in California. Many leaf hoppers (q.v.) feed upon the leaves; also several plant and leaf bugs, and plant lice, notably the common melon aphid (*Aphis gossypii*). Various cutworms (q.v.) are troublesome while the beets are young. Considerable damage has been done by the greenhouse leaf roller (*Phlyctenia ferrugalis*). The so-called garden webworms, however, especially in the West, have done the greatest damage of all. Certain leaf beetles injure the leaves, and the larvae of some of them feed upon the roots. Much damage has been done by grasshoppers, nonmigratory locusts, and blister beetles (q.v.), the imbricated snout beetle, and the army worm (q.v.). Towards the close of the last century the so-called beet army worm (*Laphygma flavimaculata*) defoliated thousands of acres of sugar beets in Colorado. The purslane caterpillar (*Copidryas gloveri*), the purslane sphinx (*Deilephila lineata*), and several of the woolly-bear caterpillars also feed upon the leaves. Great damage has been done in the State of Washington by a root louse known as the beet aphid (*Phemphigus betæ*), and a root mealy bug has been found on the crown of the plant in Colorado. Several of the wireworms (q.v.) and white grubs (q.v.) also damage the roots.

Consult Forbes, in *Twenty-first Annual Report of the State Entomologist of Illinois* (Chicago, 1900), and Forbes and Hart, *Illinois Agricultural Experiment Station, Bulletin No. 60* (Urbana, 1900).

**SUGAR BERRY.** See HACKBERRY.

**SUGAR CANE** (*Saccharum officinarum*). A tropical and subtropical grass, originally a native of the East Indies. It was brought to Europe by the Crusaders, and in the fifteenth and sixteenth centuries found its way into all the European colonies in the tropics. In Europe the cultivation of the sugar cane has always been limited almost wholly to Sicily and Andalusia. In China it extends to latitude 30° N., and in North America to 32°; in the Southern Hemisphere only to latitude 22° S.

The plant is a perennial with creeping roots, sending up a number of many-jointed diversely colored stems, generally 8 to 12 feet high, 1 to 2 inches thick, and filled for about two-thirds of their length with a loose, sweet, juicy pith. The leaves are ribbon shaped, 4 to 5 feet long, with a strong midrib. The flowers are in long and diffuse pyramidal panicles. Until quite recently the flowers were considered infertile and were regarded as unimportant. Use of the flowers and the seeds is now made in the development of new varieties and strains according to modern plant-breeding methods. In subtropical regions as the southern United States

SUGAR CANE.

the plant rarely produces seed. Even under the most favorable conditions the plant yields a relatively small number of fertile seeds and these retain their germinative power for only a comparatively short time.

Sugar cane requires a deep rich soil and abundant moisture during the growing season. Low alluvial soils near the sea are preferable. The land is prepared with large deep-going plows. The plants are propagated by cuttings. For this purpose the top joints are planted in rows 5 to 7 feet apart. Usually two continuous lines of cane cuttings are planted in the row. The largest varieties, in rich, moist soils, attain a height of 20 feet; but in dry, poor soils the height is sometimes scarcely more than 6 feet. The cane ground is kept clean by shallow cultivation. The best varieties are ready for cutting in about eight or ten months from the time of planting, but other varieties require from 12 to 20 months. When the canes are fully ripe they are cut a little above the ground, stripped of their leaves, and tied in bundles. Fresh canes, called ratoons, spring from the root, so that the plantation does not require to be renewed for several years; but the canes of the first crop are the largest, and a gradual decrease of size takes place. The ordinary practice on sugar estates is

to renew a part of the plantation every year. The sugar content of the cane ordinarily grown averages from 10 to 12 per cent. Sugar-cane production is usually carried on by large plantations. It is a business of great risks, but large profits. It requires a large and sure source of labor, especially at harvest. The yield of sugar varies greatly. In regions with a fertile soil, irrigation, and improved methods of culture about five tons of sugar per acre is produced. Yields of over ten tons per acre are authenticated. In Hawaii, where sugar-cane production has reached a high degree of perfection, yields of even 14 tons of sugar per acre are known. This is obtained only by frequent plantings and scientific fertilization and irrigation of the crop. The leaves are sometimes used for feeding cattle. Efforts made by the Louisiana Experiment Station to make silage from sugar-cane refuse were unsuccessful, owing to the alcoholic and acetic fermentation induced by the residual sugar. The pressed residue from the mill, known as *lagasse*, is used for fuel. It is also employed as a fertilizer. Consult: W. C. Stubbs, *Sugar Cane* (Baton Rouge, 1897); Noel Deerr, *Sugar and Sugar Cane* (Manchester, 1905); Léon Colson, *Culture et industrie de la canne à sucre* (Paris, 1905); Jones and Scard, *Manufacture of Cane Sugar* (New York, 1911); and bibliography of SUGAR. See SUGAR, MANUFACTURE OF and Plate of MONOCOTYLEDONS.

**SUGAR-CANE DISEASES.** No part of the sugar-cane plant is free from some kind of parasitic attack. Some diseases occur in practically every cane-growing region, while others are less widely distributed. The sugar content of the cane is lowered by some diseases but by others the chief injury is shown in the imperfect stand and dwarfed character of the growth. Leaf spot (*Cercospora longipes*), ring spot (*Leptosphaeria sacchari*), and a leaf-splitting disease caused by *Mycosphaerella* (sp.) are the principal parasitic diseases of the foliage. The more important stem diseases and their causes are: red rot (*Colletotrichum falcatum*), gummosis (*Bacillus vascularum*), smut (*Ustilago sacchari*), seroh, a very serious disease in Java, the cause of which is unknown, rind disease (*Trichosphaeria sacchari*), pineapple disease (*Thielaviopsis ethacetica*), black rot (*Sphaeroneuma adiposum*), and a disease known in Hawaii as *iliu* (*Gnomonia iliua*). Among the root diseases, that caused by *Marasmius sacchari* and related fungi is perhaps the most widely spread and serious in its effects. Selection of seed cane, treating it with fungicides, and rotation of crops give some degree of relief from these diseases. On account of the possibility of the introduction of some of these parasites the importation of sugar cane into the United States is prohibited.

**SUGAR-CANE INSECTS.** The principal enemies of the sugar cane in the United States are the sugar-cane beetle (*Ligyris rugiceps*) and the sugar-cane borer (*Diatrea saccharalis*). The former belongs to the family Scarabæidæ, and breeds in the ground. The adult beetles make their appearance in early spring, bore into the stubble or into the young cane, and also work into the seed cane; the top leaves wither and the stalk is finally destroyed. The borer is the larva of a crambid moth which lays its eggs upon the leaves of the young cane near the axils, and the young borer, hatching in the course of a few days, penetrates the stalk at or

near the joint and tunnels, usually upward, through the soft pith. It matures in 30 days or less, and there are several generations each year. It hibernates in the larval state in the lower part of the stalk or in the tap root. Burning the tops and volunteer cane, and laying down the seed cane in trenches beneath the surface of the ground, keep this insect in check.

In Hawaii there is a weevil borer (*Sphenophorus obscurus*) which does considerable damage. Stalks of the cane are frequently riddled with the galleries of the larvæ, and the galleries are filled with macerated fibre, and the larvæ apparently pushes behind itself. When ready to pupate the tunnel is somewhat enlarged and a cocoon is formed of coarse fibre in which transformation takes place. In Australia there is a noctuid larva which bores downward from the tips of the plants. Certain scarabæid larvæ feed upon the roots, and the young plants are destroyed by wireworms. In the West Indies a bark-boring beetle (*Xyleborus piceus*) sometimes riddles the canes by its minute burrows, the larva working into the young sprouts from the stumps of previously cut canes. In Java there are three lepidopterous borers and a mealy bug which do some damage, and in Mauritius a somewhat troublesome scale insect known as *Icerya sacchari*. Consult: *Insect Life* (Washington, 1888 to 1895), passim; Comstock, *Report on Insects Injurious to Sugar-Cane* (ib., 1881); Morgan, "Sugar-Cane Borer," in *Bulletin 9, Louisiana Agricultural Experiment Station* (Baton Rouge, 1891).

**SUGAR CORN.** See MAIZE.

**SUGAR GUM.** See EUCALYPTUS.

**SUGAR HOUSE, THE.** A brick building on Liberty Street, New York, used by the British as a military prison during the Revolution. When it was demolished, one of its barred windows was erected in Van Cortlandt Park.

**SUGAR OF GELATINE.** See GLYCINE.

**SUGAR OF LEAD.** The common name for acetate of lead. See LEAD.

**SUGARS** (OF., Fr. *sucre*, from ML. *sucarum*, *saccharum*, from Gk. *σάκχαρ*, *sakchar*, *σάκχαρον*, *sakcharon*, sugar). A term applied to various substances composed of carbon, hydrogen, and oxygen (see CARBOHYDRATES), which are more or less sweet, readily soluble in water, colorless and odorless, and usually crystallizable. They are widely distributed in nature as original products of vital processes in plants, and are important in the organic world. In green plants they are formed from carbon dioxide and water by the chloroplasts (see PHOTOSYNTHESIS), and are transferred by diffusion to all parts of the plant body to be used directly in the metabolism of the plant for the manufacture of proteid substances, or to be stored for future use, sometimes as glucose (in the onion bulb), sometimes as sucrose (in the beet), and sometimes as other widely different substances into which they have been converted. (See STORAGE.) If formed more rapidly than they can diffuse away, sugars may be condensed into starch in the chloroplasts themselves. At times of renewed growth, as in the germination of seeds and the sprouting of tubers and bulbs, the plant draws upon these stores of carbohydrate. If the storage has been in the form of cellulose, starch, inulin, or cane sugar, the stored food must be converted by means of enzymes into a hexose sugar before it can be utilized. The stored sugars of plant tissues form one of the most valuable sources of

animal food. Sugars found in the bodies of animals or in the excreta therefrom are believed to be derived from substances of vegetable origin.

All the monosaccharides (see below) and certain of the disaccharides possess the property of reducing compounds of copper, silver, and other easily reducible metals in alkaline solution, the reduction being generally more rapid at the boiling point of the liquid. In some cases the compounds are reduced to lower oxides, which are precipitated; in other cases the reduction is complete, the free metal being precipitated. An alkaline solution of copper (see FEHLING'S SOLUTION) is the one usually employed for testing the reducing power of sugars. Reduction of Fehling's solution is further used for the quantitative determination of reducing sugars. Among the important nonreducing sugars may be mentioned: sucrose (cane sugar), raffinose, melicitose, and stachyose.

All the sugars possess the property of rotating the plane of polarized light. Those that turn the plane of polarization to the right are called dextrorotatory; those to the left, levorotatory. In some cases, notably that of ordinary cane sugar, the amount of rotation is proportional to the amount of the sugar in a given volume of the solution, and this is taken advantage of for the quantitative determination of sugars. A special form of the polariscope (q.v.), called a saccharimeter, is in common use for this purpose. For the polarimetric determination of sucrose (cane sugar), a weighed quantity of the sugar, syrup, or other material is dissolved in water; the solution is treated with lead acetate or other clarifying agent, diluted to 100 cubic centimeters, filtered, and placed in the observation tube of the polariscope. The observer then ascertains the percentage of sugar contained in the material under investigation by simply looking into the instrument, and adjusting it to compensate for the change in the field of vision caused by the presence of the sugar solution. This simple method is applicable even in those cases in which the observed rotation is not proportional to the concentration of the sugar solution. Thus, the percentage of glucose in a given solution is often determined polarimetrically.

Since 1880 the sugars have formed the subject of numerous brilliant researches, notably those of H. Kiliani and Emil Fischer. In the early eighties Kiliani demonstrated conclusively the constitution of the simple sugars; he showed that d-glucose (dextrose or grape sugar) and d-fructose (lævulose or fruit sugar) are aldehyde and ketone derivatives, respectively, of hexahydric alcohols, the former containing one aldehyde group and the latter one ketone group. (See ALCOHOLS; ALDEHYDES; KETONES.) He also showed that arabinose is an aldehyde of the pentahydric alcohol, arabite, and has the formula  $C_5H_{10}O_5$ . The molecules of all carbohydrates had been believed to contain six carbon atoms or some multiple thereof. But sugars containing three, four, five, six, seven, eight, and nine atoms of carbon in their molecules are now known; these are designated respectively by the class names trioses, tetroses, pentoses, hexoses, heptoses, octoses, and nonoses. According as the individual members of each of these classes contain aldehyde or ketone groups (see ALDEHYDES; KETONES), they are designated as aldoses or ketoses; e.g., aldohexoses and ketohexoses. These classes together constitute the group

of carbohydrates known as *monosaccharides*. Their molecules contain as many atoms of oxygen as atoms of carbon, except in the case of certain of their synthetic derivatives.

There are other groups of sugars, in the molecules of which there are fewer atoms of oxygen than of carbon. When the latter are treated with acids or enzymes they are hydrolyzed, i.e., each one of their molecules combines with one or more molecules of water and simultaneously splits up into two or more monosaccharide molecules. These more complex sugars are called disaccharides when each of their molecules yields two monosaccharide molecules; trisaccharides when one molecule yields three monosaccharide molecules; or, in general, polysaccharides (see CARBOHYDRATES). For example see descriptions of individual sugars below.

Emil Fischer prepared a number of hitherto unknown sugars by purely synthetic processes. He showed that the monosaccharides furnish excellent examples of the necessity for the chemist to consider the space relations of the atoms in the molecule. (See STEREOCHEMISTRY.) According to stereochemical theory sixteen isomeric aldohexoses are possible, since their molecules contain each four asymmetric carbon atoms. Three of these occur in nature or are obtainable from natural carbohydrates by hydrolysis. Practically all the other aldohexoses foreseen by the theory have now been produced in the laboratory—mostly by Fischer, partly by Levene at the Rockefeller Institute for Medical Research.

The character of the differences between the aldohexoses is illustrated by the following stereochemical formulæ:

Formic aldehyde and glycerin, both of which have been produced synthetically, are substances from which certain sugars have been synthesized by Fischer and others. Formic aldehyde, CH<sub>2</sub>O or H.CHO, may be regarded as the simplest of the monosaccharides and be designated as monose. Baeyer (1870) suggested that this substance is the first product of the reduction of carbon dioxide in the green parts of plants, and that starch and other carbohydrates are formed by its polymerization. It is known readily to undergo polymerization or condensation to form paraformaldehyde (CH<sub>2</sub>O)<sub>n</sub>, and trioxymethylene (CH<sub>2</sub>O)<sub>3</sub>. In 1861 Butleroff obtained by condensation of trioxymethylene a sweet, sugar-like body which he called "methylenitan." Loew (1885) obtained in a similar manner "formose" from oxymethylene, and later "methose." The last named is more sugar-like than "formose" in that it is fermented with yeast. Fischer regards these substances as mixtures of different hexoses, including among others α-acrose, which he also obtained from glycerose, a mixture of glyceraldehyde and dioxycetone, obtained by the careful oxidation of glycerol (glycerin). From α-acrose [(d + l) fructose] Fischer prepared d-fructose, d-glucose, d-mannose, and the l-modifications, or optical antipodes of each of these bodies. The synthesis of each of these

bodies was accomplished by a series of complicated reactions. Fischer's work was greatly facilitated by the use of phenylhydrazine, which, in the presence of acetic acid, forms readily crystallizable compounds with the hexoses, called osazones. These compounds are insoluble in water and eminently suited for the separation and identification of the different sugars. By means of Kiliani's method known as the cyanhydrine reaction, he changed hexose sugars into heptoses, and these in turn into octoses and nonoses.

The combination of monosaccharides to form a naturally occurring disaccharide has probably been accomplished by Fischer in at least one case. Fischer calls his synthetic disaccharide *galactosidoglucose* (because it is made by the union of one molecule of d-galactose with one molecule of d-glucose). The substance closely resembles the natural sugar melibiose, and Fischer announced that if further investigations confirm his conclusion that the two sugars are identical, "melibiose is the first natural disaccharide to be produced synthetically."

The more important sugars are mentioned in the following table with brief descriptions of those of commercial importance:

#### I. MONOSACCHARIDES

1. Monose, CH<sub>2</sub>O. Formic aldehyde.
2. Biose, C<sub>2</sub>H<sub>4</sub>O<sub>2</sub>. Glycollic aldehyde.
3. Triose, C<sub>3</sub>H<sub>6</sub>O<sub>3</sub>. Glycerose, obtained by oxidation of glycerin.
4. Tetrose, C<sub>4</sub>H<sub>8</sub>O<sub>4</sub>. Erythrose, obtained by oxidation of erythrin, a tetrahydric alcohol found in lichens and algae.
5. Pentoses, C<sub>5</sub>H<sub>10</sub>O<sub>5</sub>.
  - A. Aldopentoses. l-arabinose (arabinose, arabose, pectinose, pectin sugar) and xylose (wood sugar), obtained alone or mixed with other sugars by hydrolysis of gums and other vegetable substances.  
d-arabinose, l-xylose, and ribose, obtained synthetically.
  - B. Ketopentoses. None known with certainty.
  - C. Methyl pentoses, CH<sub>3</sub>C<sub>5</sub>H<sub>9</sub>O<sub>5</sub>. Fucoose, from seaweed; rhamnose, widely distributed in the vegetable kingdom in the form of glucosides: chinovose, obtained by the decomposition of chinovite, a constituent of cinchona bark.
6. Hexoses, C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>.
  - A. Aldohexoses. d-glucose (dextrose, grape sugar or starch sugar); see GLUCOSE; d-mannose (mannose, isomannose or semimannose), obtained by the oxidation of mannite and by the hydrolysis of various vegetable materials, d-galactose (see below).  
l-glucose, l-mannose, l-galactose, d-gulose, l-gulose, d-idose, l-idose, d-talose, and l-talose, obtained synthetically.
  - B. Ketohexoses. d-fructose (levulose or fruit sugar; see below); sorbinose, from mountain-ash berries.  
l-fructose, obtained synthetically.
  - C. Hexoses of natural origin and of unknown nature. Chondroglucose, crocose, eucalyn, hederose, indigluin, locose, paragluose, phlorose, scammonose, skimmimose, solanose, tewfikose (forms 5 to 6 per cent of the milk of the Egyptian buffalo), and vine sugar.
  - D. Methyl hexoses, CH<sub>3</sub>C<sub>6</sub>H<sub>11</sub>O<sub>6</sub>. α-rhamno-hexose and β-rhamno-hexose, obtained synthetically.
7. Heptoses, C<sub>7</sub>H<sub>14</sub>O<sub>7</sub>. Six heptoses and a methyl derivative have been prepared synthetically.
8. Octoses, C<sub>8</sub>H<sub>16</sub>O<sub>8</sub>. Four octoses and a methyl derivative have been prepared in the laboratory.
9. Nonoses, C<sub>9</sub>H<sub>18</sub>O<sub>9</sub>. Two have been produced artificially.

#### II. DISACCHARIDES

1. Derivatives of pentoses, C<sub>10</sub>H<sub>18</sub>O<sub>5</sub>. Di-arabinose or arabinon, obtained from arabinic acid (metaplectic acid).

2. Derivatives of hexoses,  $C_{12}H_{22}O_{11}$ .

Sucrose (cane sugar, saccharose, saccharon, or saccharobiose), lactose (milk sugar, lactobiose, or lacton), and maltose (maltobiose, malt sugar, amydon, diglucon, ptyalose, or cerealose; see below).

Trehalose (mycose, trehaliose) from ergot and other fungi; isomaltose from malted grain; melibiose, formed together with d-fructose by careful hydrolysis of raffinose; turanose, formed together with d-glucose by hydrolysis of melicitose; cyclamose, from cyclamen tubers; agavose, from the juice of the agave; and several produced synthetically by Fischer.

## III. TRISACCHARIDES

All are derivatives of the hexoses,  $C_{18}H_{32}O_{16}$ .

Raffinose (melitriose, melitose, and gossypose, or cotton sugar, see below); melicitose (melcitriose), from the manna of *Pinus larix*; stachyose, from the tubers of *Stachys tuberosa*; gentianose, from the roots of *Gentiana lutea*; lactosinose (lactosin), from the roots of certain plants of the order Caryophyllaceae; and sealoase, from unripe rye.

**Sucrose, Cane Sugar, or Saccharose.** This is commercially the most valuable sugar. It and the products of its hydrolysis, "invert sugar" (d-glucose and d-fructose), are the most important sugars, considered from the point of their wide distribution in fruits and vegetables used for food by man and the lower animals. (For the commercial sources of cane sugar, see SUGAR, MANUFACTURE OF.) White granulated sugar, whether made from sugar cane or beetroots, contains between 99 and 100 per cent of pure sucrose or cane sugar. In many plants it is found associated with "invert sugar," which seems to be changed to cane sugar during the process of ripening. When cane sugar is hydrolyzed by the action of acids or enzymes, each molecule yields one molecule of d-glucose and one molecule of d-fructose, a mixture called "invert sugar."

Cane sugar is readily crystallized in the form of monoclinic hemihedral tables which contain no water of crystallization. These crystals are well exemplified in loaf sugar, rock candy, and granulated sugar, the coarseness of which depends upon the size of the crystals. It dissolves in about one-half of its weight of water and is even more soluble in hot water; it dissolves with difficulty in strong alcohol. Its specific gravity is about 1.6. It melts at  $160^{\circ}\text{C}$ . ( $320^{\circ}\text{F}$ .), and with care may be cooled to a colorless glasslike mass; if the temperature is somewhat higher the solidified mass is colored and constitutes the so-called "barley sugar." At  $200^{\circ}\text{C}$ . ( $392^{\circ}\text{F}$ .), decomposition and marked discoloration set in, caramel is formed, and as the heat is continued gases are evolved and finally only a black char remains. Sucrose unites with the oxides of calcium and other metals to form saccharates, which are of importance as a means of separating sugar from beetroot molasses. While cane and other sugars in dilute solutions are very prone to undergo fermentation and change, they possess considerable antiseptic power in concentrated solution, which is utilized in keeping dried fruits, preserves, etc.

**Levulose, d-Fructose, or Fruit Sugar.** This occurs in almost all sweet fruits with d-glucose. It is crystallized with difficulty, and melts at  $95^{\circ}\text{C}$ . ( $203^{\circ}\text{F}$ .). It is readily obtained by hydrolysis of inulin, a polysaccharide which oc-

curs in many plants. It is less soluble than d-glucose, and is as sweet as cane sugar. Levulose is used as a substitute for sugar in the food of diabetic patients. Some of the commercial forms of levulose for this purpose are called "diabetinc."

**Raffinose, Melitriose, Melitose, or Cotton Sugar.** This occurs in rather large quantity in Australian manna (from varieties of *Eucalyptus*), in cottonseed meal, and in small quantities in sugar beets, the manufactured sugar from which sometimes contains small amounts, but the molasses much the greater proportion. It forms characteristic crystals and is strongly dextrorotatory. When hydrolyzed by acids each molecule yields one molecule of d-glucose, one of d-fructose, and one of d-galactose.

**Maltose, Maltobiose, or Malt Sugar.** This is formed, together with dextrin and dextrose, when starch is hydrolyzed with enzymes or acids. It is present in malted grain, in commercial glucose, and in the mash of beer and whisky. It is usually obtained in the form of crystalline crusts. When hydrolyzed it is converted into d-glucose.

**Milk Sugar, or Lactose.** This occurs in the milk of mammals. It crystallizes in white hard rhombic prisms, with one molecule of water of crystallization, which is dissipated at  $140^{\circ}\text{C}$ . ( $284^{\circ}\text{F}$ .); at  $205^{\circ}\text{C}$ . ( $400^{\circ}\text{F}$ .), it melts with decomposition. It dissolves in six parts of water at the ordinary temperature and in  $2\frac{1}{2}$  parts of hot water, is insoluble in alcohol, and has a faint, sweet taste. When hydrolyzed by the action of acids it is converted into equal parts of d-glucose and d-galactose. See SUGAR, MANUFACTURE OF.

**Galactose.** This is of interest as one of the inversion or hydrolysis products of raffinose and milk sugar. It is also obtained by the hydrolysis of a number of polysaccharides occurring in vegetable substances and called "galactans."

Pavy, *Physiology of the Carbohydrates* (London, 1895); L. G. M. Maquenne, *Les sucres et leurs principales dérivés* (Paris, 1900); J. E. Mackenzie, *Sugars and their Simple Derivatives* (Philadelphia, 1914).

**SUG'DEN**, EDWARD BURTENSHAW. A celebrated English jurist and author. See SAINT LEONARDS, EDWARD BURTENSHAW SUGDEN, BARON.

**SUGER**, su'zhâ', ABBÉ DE SAINT-DENIS (1081-1151). A French churchman, statesman, and historian. He spent a large part of his youth in the abbey of Saint-Denis and was for a time a student with Prince Louis, afterward Louis the Fat, with whom he always remained on terms of close friendship. In 1122 he became abbé of Saint-Denis, and he carried out many reforms and greatly increased the prosperity of his charge. He was frequently engaged in affairs of state, and when Louis VII went on the Second Crusade, Suger acted as Regent in his absence and administered the affairs of the Kingdom with great ability. Shortly afterward, although he had opposed the previous one, Suger preached another crusade, but died in 1151 before it could be carried out. He wrote in Latin a *Life of Louis VI* (c.1140), which is one of the chief sources upon the history of the period. His complete works were published at Paris in 1867.

**SUGGESTION** (Lat. *suggestio*, intimation,

suggestion, from *suggerere*, to suggest, supply, from *sub*, under + *gerere*, to carry). Any stimulus which sets in function a determining tendency (q.v.). Less technically, a prompting, other than a direct impression, which conditions an organic movement or a change in the content or meaning of consciousness. Thus a yawn may suggest going to bed, a shiver suggest cold, or a sound in a lonely house suggest ghosts.

The arousal of sensation by suggestion is doubtful. In the laboratory an observer whose finger has been introduced into a box in which he has seen a burning candle may report warmth, even when the flame has (without his knowledge) been extinguished. In such cases, however, there are several possibilities. The sensation may be imagined; or attention may be directed by the suggestion to previously unnoticed sensations of the suggested quality; or other sensations may be falsely interpreted as of that quality. Finally, the suggestion may lead directly to report, or to other action indicative of the quality, without the basis either of sensation or of image. Experimental work upon sensory suggestion tends to show that all of these possibilities are at times realized. There is evidence in support of the suggestive arousal of sensations proper; though, in view of the similarity of sensation to image (q.v.), the point is difficult to determine.

The use of the term "suggestion" to indicate the fact of association (see ASSOCIATION OF IDEAS) is psychologically out of date. It is now seen that in both "free" and "constrained" association the organism is set or instructed, so that the ideas always arise under determination. Attention and action (qq.v.) are also essentially determined consciousnesses. It follows, therefore, that suggestion is natural and necessary throughout the normal mental life, and is not the mysterious and sporadic phenomenon that common usage makes it. In abnormal states, such as hypnosis and hysteria, the nature of suggestion remains precisely the same, only that its effects are enormously magnified by the weakness or absence of contradictory ideas, and by the extreme vividness of the suggestions themselves.

In general, suggestion is to be explained in terms of inhibition and facilitation of certain nervous excitations, with consequent restriction of the scope and definition of the direction of nervous function; but nothing further can be stated with assurance. See DETERMINING TENDENCY; HYPNOTISM; and references there given.

**SUHL**, *suhl*. A town of the Prussian Province of Saxony, Germany, on the Lauter, 12½ miles north by east of Meiningen (Map: Germany, D 3). Important for its manufactures of swords and firearms since the fifteenth century, Suhl has been called the "armory of Germany." Pop., 1900, 12,617; 1910, 14,468.

**SUICIDE** (from Lat. *sui*, of one's self + *-cidium*, a killing, from *cedere*, to kill). The intentional taking of one's own life. Among uncivilized peoples suicide is by no means unknown, though generally regarded as uncommon. It is favored by the teaching of some Oriental religions, but expressly forbidden by the Koran. Aristotle condemned suicide as unmanly, and early Greek custom accorded dishonorable burial to the perpetrator; but later practice, especially under the influence of the Stoics, was much less severe. The Romans, also affected by Stoic doctrine, recognized many legit-

imate reasons for suicide and punished with confiscation of property only suicides committed to escape punishment for a grave crime. Under Christianity the spirit of law and custom was radically modified. To St. Augustine suicide was essentially a sin, and several Church councils, from the fifth century, deprived the corpse of the ordinary rites of the Church. Mediæval law usually provided confiscation of the suicide's property, while custom decreed indignities to the corpse, such as dragging by the heels face downward, as in France, or burying at the crossroads with a stake through the body, as in England. Later English law compelled forfeiture of lands and goods in all cases of suicide, but the requirement came to be frequently evaded through the granting of a coroner's verdict of insanity, and the law itself was abolished in 1870. A statute of 1823 made it legal to bury suicides in consecrated ground, but it was not till 1882 that religious services were expressly permitted. In France at the present time neither suicide nor attempt at suicide is punishable. In the United States suicide is unlawful, and an unintentional killing of another during an attempt at self-destruction is homicide. An attempt at suicide is a common-law misdemeanor, and in some States a felony by statute. Thus in New York, aiding a suicide is manslaughter in the first degree, aiding an attempt at suicide is felony, and the attempt itself by a sane person is felony, punishable by not over two years in State prison, or a fine of not over \$1000, or by both.

The statistics of suicide are by no means satisfactory, as motives always exist for concealment of causes, and published figures are usually too low. This trouble is partly overcome with comparative figures, as below, showing the average annual number of suicides per million of population in various countries during the nineteenth century:

COUNTRY	1851-55	1861-65	1871-75	1887-91	1901-10
England and Wales.....	64	66	66	81	†90

\* 1856-65.

† United Kingdom.

The differences which appear between countries are due rather to race and national characteristics than to climate. This is well shown by suicide rates in the United States. In 1900 in the registration area persons with mothers born in France had a suicide rate (per million) of 220; Germany, 193; England and Wales, 104; Ireland, 61; Russia and Poland, 58; Italy, 51. In the registration area as a whole the rate was 103 in 1890 and 118 in 1900, being very much higher for white persons than for colored. In 1913 it was 158 for the registration area, 162 for whites, and 86 for colored. The most notable difference of rate is that occasioned by sex, males usually constituting from three-quarters to four-fifths of the total suicides. In 1913 male suicides in the registration area of the United States numbered 7709; female, 2279. Statistics indicate that the preponderance of males has

been increasing. When age is considered together with sex, it appears that, while suicide in general increases with age, the ages at which women most tend to self-destruction are much under the corresponding ones for men. Thus in the United States (1913) female suicides exceed male up to age 19. Up to age 39 the female suicide rate diminishes from half to one-third of the male rate, and beyond age 40 declines to one-sixth, at ages 80-84. Married people show a lower suicide rate than single, and single than widowed or divorced persons. Large cities have an unfavorable influence. The rate in Dresden is more than 500 per 1,000,000; in Paris, more than 400; in London, about 230; in Berlin, 260; in St. Petersburg and Rome, less than 100. In New York City the rate for 1914 was 176; in Chicago, 242; in Philadelphia, 165; in St. Louis, 366; in Boston, 181.

Suicides among the young are prevalent in the great centres. Professional and commercial classes are more prone to suicide than others; artisans evince higher rates than laborers; among soldiers and criminals the rates are extremely high. The rates for summer or late spring are much above those for the other seasons, the maximum usually between April and July, the minimum in January or December. The early part of each month and the early days of the week show a relative preponderance. Other interesting correlations appear in the methods by which suicide is accomplished. In the aggregate the order of preference in method is: hanging, drowning, shooting, cutting or stabbing, falling from a height, and asphyxiation or poison. In cold countries drowning is naturally less favored than in the south; the use of firearms is specially prominent in Italy; of cutting or stabbing in Prussia; of poison in England. As would be expected, female suicides employ firearms less than male. In England drowning is the recorded means for more than a quarter of the women committing suicide, and poison for about a seventh; but only 15 per cent of male suicides drown themselves, and only a twelfth use poison.

Definite mental disorders usually appear as the direct cause of a third of all suicides, but a much larger proportion of cases show evidence of mental or physical abnormality. Suicidal tendency, like insanity, has been observed to be inherited. Alcoholism is a frequent cause. Emphasis upon biological influences has led some writers to regard suicide as always being, like certain diseases, a specific tendency of the individual. But the social causes of suicide are not to be underestimated. Imitation and the desire for notoriety undoubtedly affect suicides, and the stress and strain of modern business.

**SU'IDÆ.** The swine family. See SWINE.

**SU'IDAS** (Lat., from Gk. Σοιδας, *Soidas*). The author of a great Greek lexicon, compiled probably in the middle of the tenth century. The work current under his name is a compilation giving the result of grammatical, lexicographical, historical, and literary studies. It is valuable for articles touching the latter field, and the information they contain is indispensable for knowledge of the writers of antiquity. It is clear that the lexicographical portions were drawn from the lexica of Harpocration and Helladius, and from certain other lexica and grammatical works which cannot be absolutely determined. He further employed excellent scholia to Aristophanes, scholia to Sophocles similar to those now found in the *Codex Laurentianus*, Homeric scholia similar to those found in the *Codex Venetus B*, and the older scholia to Thucydides. In his historical and theological articles it is more difficult to determine his sources, but his chief authority seems to have been the work of Constantinus Porphyrogenitus and the chronicle of Georgius Monachos. His literary articles were probably drawn in large measure from the Onomatologos of Hesychius Milesius, which he possessed in an abridged form. He employed also the notices of the comic poets preserved in Athenæus; but he added much from his independent reading. The work is best edited by Bernhardt (1834-53). The edition by Bekker (1854) is far inferior. Consult Adam Daub, *De Suidæ Biographicorum Origine et Fide* (Heidelberg, 1880); id., *Studien zu dem Biographika des Suidas* (Freiburg, 1882); J. E. Sandys, *A History of Classical Scholarship*, vol. i (2d ed., Cambridge, 1906).

**SUI JURIS**, sūi jōr'is (Lat., of his own right). A Latin phrase employed to describe a person competent to perform legal acts. (See CIVIL LAW; PATRIA POTESTAS.) The meaning of the phrase has been extended in modern times to denote a person who is capable of taking care of himself. Thus a minor or an insane person is designated in law as a person non sui juris.

**SUIR**, shōōr. A river of Ireland. Rising in County Tipperary, it forms, in part, the boundary between that county and County Waterford and then the boundary between Waterford and County Kilkenny (Map: Ireland, D 7). It unites with the Barrow to form Waterford Harbor, after a course of about 100 miles.

**SUISSE**, swēs, JULES FRANÇOIS SIMON. See SIMON, JULES.

**SUIT.** In law, any proceeding in a court of justice brought for the purpose of obtaining a specific remedy by way of damages or other relief. All such proceedings are now generally designated as civil actions rather than as actions at law and suits in equity. Thus it has been held that the words "action" and "suit" in statutes of limitation are synonymous. See ACTION; EQUITY.

**SUITE**, swēt (Fr., succession, following), or PARTITA. In music one of the oldest of cyclical forms. It had its origin in the sixteenth century, when the Stadtpfeifer began to perform several national dances in succession,

which were of contrasting tempi, but all in the same key. During the seventeenth century German composers for the pianoforte applied the name *partita* to their doubles (a series of variations). (See VARIATION.) The form reached its culmination in the suites of J. S. Bach. The style of the suite is not so much contrapuntal as elegant. The four obligatory movements are: (1) *allemande*, (2) *courante*, (3) *sarabande*, (4) *gigue*. As a rule, however, there were more movements, which were inserted after the *sarabande*. Such additional movements were known as *intermezzo* (q.v.). In modern times composers have also written suites for orchestra, which, however, but slightly resemble their prototypes. Some of the movements are not dance forms, and the principle of contrasting keys is also introduced. See DANCING, *Modern Dances*; SONATA.

**SUK, ŽUK, JOSEF** (1874- ). A Bohemian violinist and composer, born at Křečovic. He began his musical studies with his father and later entered the Prague Conservatory, where he studied violin with Bennewitz and composition with Knittl, Strecker, and Dvořák, whose daughter he subsequently married. In 1892 he became a member (second violin) of the famous Bohemian Quartet. Later he also appeared frequently as a concert conductor. His works include two symphonies (E flat and E minor); *Serenade* for strings; *Scherzo Phantastique*; a symphonic poem, *Praga*; incidental music to Zapor's *Rádus und Mahulena* and Zeyer's *Pod jabloni* (Under the Apple Tree); some noteworthy chamber music; and the opera *Lesur pán* (The Master of the Forests), produced at Prague in 1903.

**SUKASAPTATI**, *shōō'kā-sūp'tā-tē* (Skt., 70 [stories] of a parrot). A collection of Sanskrit prose stories, 70 in number, told by a parrot to the wife of a merchant who is away on his travels. She is inclined to be adulterous, and consults the parrot regarding her plans. The bird pretends to approve of her intentions, but points out to her the dangers of detection, and induces her to promise not to meet any lover unless she can extricate herself as so-and-so did. This rouses her curiosity, and the parrot tells the story as far as the dilemma, when he asks her what, in her opinion, the person involved ought to do. Unable to make a suitable guess, she promises to remain at home that night on condition that the parrot will tell her the answer the following evening. In this way 70 days pass until her husband returns. The story is very popular in India and has been translated into Persian as the *Tūtīnāmah*. The *Sukasaptati* exists in two recensions. The shorter one was edited (Leipzig, 1893) and translated (Kiel, 1894) by R. Schmidt, who also edited (Munich, 1896) and translated (Stuttgart, 1899) the longer version. Consult: Schmidt, *Ueber die Śukasaptati* (Halle, 1898); Victor Henry, *Les littératures de l'Inde: sanscrit-pāli-prācrit* (Paris, 1904); A. A. Macdonell, *History of Sanskrit Literature* (London, 1913). A selection from this collection of stories has also been published under the title *The Enchanted Parrot* by Wortham (London, 1911).

**SUKHĀVATĪ**, *sōōk-hū'vā-tē'* (Skt., blissful). The Land of Bliss into which those Buddhists are reborn who believe in Amitabha Buddha, the Buddha of boundless light, life, and mercy, invented by the founders of the Northern or

Mahayana (q.v.) School. It is situated in some far distant world separated from this world by tens of millions of Buddha worlds, and is presided over by Amitabha. Here there is no difference between gods and men. There is no sin, no hunger, nor pain of any kind, and neither summer nor winter, no day, no night. To attain to this paradise good deeds in this life are not necessary. Simple trust in the mercy of Amitabha is sufficient. Among the common people this doctrine has superseded the doctrine of Nirvana (q.v.). Consult D. T. Suzuki, *Outlines of Mahāyāna Buddhism* (London, 1907).

**SUKHOMLINOV**, *sōō'kōm'lyē-nōf*, VLADIMIR ALEXANDROVITCH (1852- ). A Russian general. During the Russo-Japanese War he commanded the forces guarding Russia's western frontier, and afterward held various military positions in Russian Poland and on the Prussian frontier. As Governor of Kiev, he became notorious for his inflictions of the death penalty. He succeeded General Rudiger as Minister of War in 1909, resigning this post in 1915, during the European War. As head of the Officers' Cavalry School Sukhomlinov provided thoroughly practical training and by throwing open the Academy of the General Staff to a larger body of military students, he promoted efficient military training. During his ministry he was permitted to expend about \$300,000,000 annually on the service, which he raised to extraordinary efficiency. Among the specific achievements to his credit were the organization of a first-class school of military aviation, the opening of a school for railroad engineers, and the development of an effective corps of army automobilists. Sukhomlinov became known as "the Russian Kitchener." Consult V. D. Doumbadze, *Russia's War Minister* (Eng. trans., London, 1915).

**SULEIMAN**, *sōō'lā-mān'*. A Turkish sultan. See SOLYMAN II.

**SULEIMANIEH**, *sū-lā'mā-nē'ye*. A town of the Vilayet of Mosul, Turkey in Asia, 130 miles southeast of Mosul. It commands several trade routes between Mesopotamia and Persia and is an important military station. Population, about 10,000.

**SULEIMAN PASHA**, *sōō'lā-mān' pā-shā'* (c.1840-92). A Turkish general, born at Constantinople. He was trained at the military school in Constantinople, entered the army, becoming major in 1867, when he served in Crete. In 1873 he was a colonel and instructor in the military school, of which he later became subdirector, with the rank of general of brigade, in 1874. He took part in the deposition of Abdul Aziz, May 30, 1876, and was made general of division by Amurath V. In 1877 he was made marshal. In the early part of the Russo-Turkish War (q.v.) he fought against General Gurko, whom he defeated at Eski-Zaghra (July 31-Aug. 1, 1877) and forced to retreat into the Balkans, failing in his attempts to command the Shipka Pass. From October to December he commanded the Turkish army of the Danube and was then intrusted with the command of the Turkish forces south of the Balkans. At Philippopolis, Jan. 15-17, 1878, he met defeat. This led to a sentence of imprisonment, but he was afterward pardoned.

**SULFONAL**. See SULPHONAL.

**SULIMAN (sōō'lā-mān') MOUNTAINS**. A range of mountains in India, separating the provinces of Baluchistan and Punjab (Map: India, A 2). It forms part of the east boundary

of the great Iranian Plateau, towards which it sends numerous spurs, while on the east it falls steeply into the Indus valley. Its highest point, the Kaisargarh, has an altitude of 11,300 feet.

**SULINA**, *sŭl'-lĕ-ná*. The central arm of the delta of the Danube (Map: Balkan Peninsula, G 2). Though not the largest in volume, it is the principal channel for navigation and has been made navigable for the largest vessels by means of large jetties and other engineering works. The European Commission of the Danube has deepened and corrected it so that at Sulina the depth has been increased from 9 to 24 feet, and below Braila the maximum depth from 8 to 18½ feet, while by canalization the navigation has been shortened from 45½ to 33¾ nautical miles.

**SULIOTES**, *sŭl'-lĕ-ŏts*. A tribe of Turkish subjects of mixed Greek and Albanian blood, who derived their name from the Suli Mountains, near Parga, in Epirus, to which they fled from the Turks in the seventeenth century. Their persistent opposition to Turkish rule brought them into constant trouble and won for them a reputation for bravery and patriotism. Overcome in 1803 by Ali Pasha of Janina, they left their mountains and fled to the islands off their native shore. From here the Suliotes were driven by the Sultan to their old mountain retreats and to the island of Cephalonia. Later they are found warring on the side of Greek independence, their most celebrated leader being Marco Bozzaris (q.v.). Many of them have migrated into Greece. Consult Perrhaebos, *History of Suli and Parga* (London, 1823), and Lüdemann, *Der Suliotenkrieg* (Leipzig, 1825).

**SULKY**. See CART.

**SULLA** (*Hedysarum coronarium*). A perennial leguminous fodder plant, native of southern Italy and similar Mediterranean regions, where it has been in cultivation since about 1766. It is a leafy plant four to six feet tall, bearing numerous clusters of showy flowers. Because it is susceptible to frost it is adapted to few regions of the United States.

**SULLA**, LUCIUS CORNELIUS (surnamed **FELIX**) (138-78 B.C.). A Roman general and statesman, born at Rome of a family belonging to the Gens Cornelia. In 107 B.C. he was elected *quæstor*, and sent to Africa with cavalry that the consul Marius (q.v.) required for prosecuting the war with Jugurtha (q.v.). He induced Bocchus, the Mauretanian King, to surrender Jugurtha (106 B.C.). In the campaigns that followed (104-101 B.C.) against the Cimbri and the Teutones, Sulla's reputation continued to rise. For several years after the destruction of the barbarians Sulla lived quietly, taking no part in public affairs; but in 93 B.C. he won the *prætorship* by a liberal distribution of money among the people. Next year he was sent to Cilicia as *proprætor*, to put Ariobarzanes back on the throne of Cappadocia, from which he had been driven by Mithridates. In the Social War (q.v.) the successes of Sulla threw those of Marius into the shade, and the mortification of the latter was bitter. In 88 B.C. Sulla was elected consul with Q. Pompeius Rufus, and the Senate conferred on him the command of the Mithridatic War. Allying himself with the tribune P. Sulpicius Rufus, a political adventurer in difficulties, Marius placed himself at the head of the new Italian party, on whom the rights of Roman citizenship had

been conferred, and Sulla was compelled to flee to his camp at Nola in Campania. There, finding the soldiers full of enthusiasm, he resolved to lead them against the pseudo-government at Rome. The Marian party was overthrown and Marius fled to Africa. Sulla was in the East, 87-83 B.C., and finally forced Mithridates to sue for peace, and returned to Italy 83 B.C. Marius was now dead, but his party was strong and again in revolt; yet before the close of 82 B.C. the Marian party in Italy was utterly crushed. In Spain, however, it held out under Sertorius (q.v.). Sulla caused himself to be appointed dictator, an office which he held until 79 B.C. In 81 came the fearful period of the proscriptions, the object of which was to extirpate the Marian party. His dictatorship was signalized by the framing of a series of laws the design of which was to restore the ancient power of the senate and the aristocracy. Consult: Plutarch, *Life of Sulla*, edited by H. A. Holden (New York, 1886); A. H. Beesly, *The Gracchi, Marius, and Sulla* (ib., 1878); C. W. Oman, *Seven Roman Statesmen* (London, 1902); and the article "Cornelius III," in Friedrich Lübker, *Reallexikon des klassischen Altertums*, vol. i (8th ed., Leipzig, 1914).

**SULLIVAN**. A city and the county seat of Moultrie Co., Ill., 25 miles southeast of Decatur, on the Wabash, the Chicago and Eastern Illinois, and the Illinois Central railroads (Map: Illinois, G 6). It contains the Illinois Masonic Home and Hospital, and has grain elevators, a flour mill, machine shops, and a planing mill. Pop., 1900, 2399; 1910, 2621.

**SULLIVAN**. A city and the county seat of Sullivan Co., Ind., 26 miles south of Terre Haute, on the Chicago and Eastern Illinois, the Illinois Central, and the Chicago, Terre Haute, and Southeastern railroads (Map: Indiana, C 6). It is a shipping point for coal, grain, and live stock; and manufactures woolen goods and brushes. The town has a Carnegie library, an Elks home, and a city hospital. Pop., 1900, 3118; 1910, 4115.

**SULLIVAN**, SIR ARTHUR SEYMOUR (1842-1900). A distinguished English composer. He was born in London of Irish parents, May 13, 1842. In 1856, at the age of 14, Sullivan won the Mendelssohn scholarship, then recently established. In 1858 he went to Leipzig, where he studied at the conservatory. His incidental music to Shakespeare's *Tempest* was his last work at the conservatory, and was first heard in England in 1862, a few days after his arrival in the country. After holding organ appointments at St. Michael's and St. Peter's he was appointed professor of the pianoforte and ballad singing at the Crystal Palace School of Art. In 1876-81 he was director of the National Training School for Music. Cambridge (1876) and Oxford (1879) honored him with the degree of Mus. Doc., and in 1883 he was knighted. He died in London, Nov. 22, 1900. His first great success in composition was his "Orpheus with His Lute," which was soon followed by "The Lost Chord." He was meanwhile engaged on more serious work, and in 1864 the cantata *Kenilworth* was produced. Then came the *Symphony in E* (1866), the overture *In Memoriam* (1866), *The Prodigal Son* (1869), *Light of the World* (1873), *The Martyr of Antioch* (1880), *The Golden Legend* (1886), and the grand opera *Ivanhoe* (1891). He is held in greatest repute, however, for his light operas, several of which

are veritable gems. But it should be said that their perennial success is the tribute paid no less to Sullivan's music than to the inimitable librettos of his collaborator W. S. Gilbert (q.v.). The principal works are: *Trial by Jury* (1875); *The Sorcerer* (1877); *H. M. S. Pinafore* (1878); *Parates of Penance* (1880); *Patience* (1881); *Iolanthe* (1882); *The Mikado* (1885); *The Yeomen of the Guard* (1888); *The Gondoliers* (1889); *Utopia* (1893); *The Beauty Stone* (1898); *The Rose of Persia* (1899); and *The Emerald Isle* (posthumous, completed by E. German, 1901). Sullivan's music is essentially lyric in quality, and he was exceptionally fluent in melody as well as a master of dainty orchestration. His early training in the school of English church music left its imprint on all his sacred compositions, and, indeed, on his operettas also. Consult: Arthur Lawrence, *Sir A. Sullivan, Life-story, Letters, and Reminiscences* (London, 1900); B. W. Findon, *Sir A. Sullivan, His Life and Music* (ib., 1903); H. S. Wyndham, *Arthur Sullivan* (ib., 1904); Cellier and Bridgman, *Gilbert and Sullivan and their Operas* (Boston, 1914).

**SULLIVAN, EDWARD** (1832-1902). A Canadian Anglican bishop. He was born at Lurgan, Ireland, and graduated at Trinity College, Dublin, in 1857. Going to Canada in 1858, he was ordained a priest of the Church of England in Canada in 1859, and in 1862 became assistant rector of St. George's Church, Montreal. In 1868-78 he was rector of Trinity Church, Chicago, and in 1878-82 rector of St. George's, Montreal. In the latter year he was appointed Bishop of Algoma, but in 1896 resigned the bishopric and became rector of St. James' Cathedral, Toronto. He belonged to the evangelical school, and attained a wide reputation as a pulpit orator.

**SULLIVAN, JAMES** (1744-1808). An American jurist and politician, born at Berwick, Me. He was admitted to the bar, and in 1770 was appointed king's attorney. In 1775 he was a member of the Massachusetts Provincial Congress, and was one of three commissioners dispatched on a secret mission to Ticonderoga. From 1776 to 1782 he was a judge of the Superior Court, and in 1784-85 a Massachusetts delegate to the Continental Congress. For many terms he was a member of the State Legislature, in 1787 was a member of the executive council and a probate judge, and from 1790 to 1807 was Attorney-General. In 1807 and 1808 he was Democratic-Republican Governor of Massachusetts. He published *Observations on the Government of the United States* (1791); *The Altar of Baal Thrown Down* (1795); *Impartial Review of the Causes of the French Revolution* (1795). Consult T. C. Amory, *Life of James Sullivan* (Boston, 1859).

**SULLIVAN, JAMES EDWARD** (1860-1914). An American athletic official and publisher, born in New York City. In 1877-84 he won a long series of victories in walking and running contests. Of the Amateur Athletic Union of the United States, which he organized in 1889, he was president in 1907-09, and for 25 years he officiated at American track meets and field games. He was prominently identified with the Olympic games (See OLYMPIC GAMES, *Modern Olympic Games*), in the revival of which he had an important part, and with the athletics at all the great American expositions from 1893. He founded the *Athletic News*, one of the first

papers of the sort in the United States, and for many years was editor, and later president, of the *New York Sporting Times*. In addition, Sullivan published *Spalding's Athletic Library*, edited *Spalding's Official Athletic Almanac*, and wrote *The Olympic Games, Stockholm, 1912* (1912). He was called the "father" of American amateur athletics.

**SULLIVAN, JOHN** (1740-95). An American soldier, born at Berwick, Me. In June, 1775, he was appointed brigadier general by Congress. During the siege of Boston, with General Greene, he commanded the left wing under Gen. Charles Lee, and on June 4, 1776, took command of the army in Canada, whence, after being defeated at Three Rivers, he retreated to New York. On August 10 he became a major general, and on the 27th served with distinction at the battle of Long Island (q.v.), but was taken prisoner. He was exchanged and served at Trenton, Princeton, Brandywine, and Germantown. In 1778 he acted with D'Estaing against Newport, and decisively defeated the English at Butt's Hill on August 29. In 1779 he marched into western New York and effectually subdued the Iroquois. Resigning from active duty late in 1779, he served in the Continental Congress in 1780-81, was Attorney-General of New Hampshire from 1782 to 1786, was President of the State from 1786 to 1789, and was United States District Judge from 1789 to 1795. Consult his *Life* by Peabody in Sparks, *American Biography*, vol. iii (new ed., New York, 1902); Amory, *Military Services and Public Life of General John Sullivan* (Boston, 1868); and *Journals of the Military Expedition Against the Six Nations* (Auburn, N. Y., 1887).

**SULLIVAN, JOHN L. (LAWRENCE)** (1858-1918). An American prize fighter, born in Boston, Mass. In 1880 he defeated George Rooke, and two years afterward he beat Ryan in nine rounds. In 1887 he fought a draw with Cardiff; in 1888 fought a draw with Mitchell at Chantilly, near Paris; and in the next year, in Mississippi, in a 75-round fight, defeated Kilrain, winning the American championship and a diamond belt offered by a sporting paper. In 1892 he met Corbett at New Orleans and was defeated in the twenty-first round, thereby losing the championship title. Later he became an advocate of prohibition, asserting that his use of liquor had been responsible for his defeat in the ring. Consult his *Life and Reminiscences of a Nineteenth Century Gladiator* (Boston, 1892).

**SULLIVAN, ROBERT BALDWIN** (1802-53). A Canadian statesman and jurist. He was born at Bandon, Ireland, went to Canada with his father in 1819, and settled at York (Toronto). He was called to the bar in 1828, practiced law in Vittoria and later in Toronto. Bred a Liberal, Sullivan at his entrance upon public life had been led to modify his political views, and soon came to identify himself with the Conservatives. He was elected Mayor of Toronto in 1835, and in 1836 was appointed a member of the provincial executive council by the Lieutenant Governor, Sir Francis Bond Head, of whom he became a trusted political adviser. He served in the militia during the rebellion of 1837-38, and was appointed a member of the Legislative Council of Upper Canada in 1839. The real test of his ability and character came with the larger issues involved in

the Act of Union in 1841 (see CANADA, *History*). Sullivan was a member of the first administration after this; but because he was a Conservative his presence, with that of others, was objected to by Robert Baldwin, the Premier, who resigned. Sullivan remained in office, and in the first Lafontaine-Baldwin administration (1841-43) was president of the council, by accepting which position he apparently repudiated his former political faith. Nevertheless he soon became more in sympathy with Liberal members of the cabinet and resigned with them upon a serious difference of opinion with the Governor-General, Sir Charles Metcalfe. Canada was now virtually without a responsible administration, the country being divided into two parties, those who favored and those who opposed the autocratic Toryism of Sir Charles Metcalfe. Sullivan at this time did the most noteworthy service of his career by a brilliant defense of parliamentary government in a series of letters contributed to the Toronto *Examiner* under the signature "Legion." In the second Lafontaine-Baldwin government (1848-51) he was Provincial Secretary for Upper Canada till 1848 and thereafter was a puisne judge of the Court of Queen's Bench for Upper Canada. He was described by authoritative writers as probably the most brilliant man known to the Canadian history of his time. As an orator he was without a rival, but the effect of his eloquence and debating power was somewhat weakened by a lack of steadfast conviction. Consult J. C. Dent, *The Last Forty Years* (Toronto, 1881).

**SULLIVAN, THOMAS BARRY** (1824-91). A British tragedian, born in Birmingham. He was brought up in Cork, where he made his appearance on the stage before 1840. He joined the company of the Theatre Royal, Edinburgh, and remained there several seasons, advancing rapidly in his profession. In 1852 he appeared at the Haymarket Theatre, London, in *Hamlet*, the part in which he was on the whole most successful, though his Beverley in *The Gamester* was very highly praised. Consult Arthur Lawrence, *Barry Sullivan: A Biographical Sketch* (London, 1893).

**SULLIVAN, THOMAS RUSSELL** (1849- ). An American novelist and dramatist, born in Boston. He was educated at the Boston Latin School, passed the years 1870-73 in Europe, was then for 15 years connected with a firm of Boston bankers as clerk and cashier, and after 1888 devoted himself to literature. The National Institute of Arts and Letters elected him to membership. He wrote, notably: *Roses of Shadow* (1885); *Day and Night Stories* (two series, 1890 and 1893); *Tom Sylvester* (1893); *Ars et Vita* (1898); *The Courage of Conviction* (1902); *Boston Old and New* (1912); *The Hand of Petrarch* (1913); and several plays, of which the more noteworthy are *The Catpaw* (1881), a dramatization of Dr. Jekyll and Mr. Hyde (1886), and *Merely Players* (1886).

**SULLIVAN, TIMOTHY DANIEL** (1827-1914). An Irish journalist and legislator. He was born at Bantry, County Cork. He early wrote for the Dublin newspapers, vigorously advocating Irish Home Rule. Later he became identified with the Land League (q.v.). In 1880, with Charles Stewart Parnell (q.v.) and others, he was arrested and tried in Dublin for his League activities, but was freed by the disagreement of the jury in January, 1881. He became prominent in the Home Rule propaganda, delivering

many speeches in Ireland and Great Britain. Between 1880 and 1900 he was a Nationalist member of the House of Commons successively for Westmeath, Dublin City, and West Donegal. He was elected Lord Mayor of Dublin in 1886 and 1887. In 1888 he was imprisoned for two months in Tullamore jail for publishing reports of branches of the Land League which had been suppressed under the Coercion Act; and in 1889 he was examined before the Parnell Commission. His publications include: *Songs and Poems* (new ed., 1901); *Recollections of Troubled Times in Irish Politics* (1905); *Bantry, Berehaven and the O'Sullivan Sept* (1908).

**SULLIVAN, SIR WILLIAM WILFRID** (1843- ). A Canadian statesman. He was born at New London, Prince Edward Island, was educated at St. Dunstan's College, and was called to the bar in 1867. He was elected a Conservative member of the Provincial Legislature and sat therein until 1889; was Premier and Attorney-General in 1879-89, and in 1889 became chief justice of the Province and local judge in Admiralty. In 1914 he was knighted.

**SULLIVAN'S ISLAND.** An island at the entrance to Charleston harbor, the site of Fort Moultrie (q.v.).

**SULLIVANT, WILLIAM STARLING** (1803-73). An American botanist, the founder of American bryology. He was born at Franklin, Ohio, studied at Ohio University, and in 1823 graduated at Yale. In 1840 he published a *Catalogue of Plants in the Vicinity of Columbus, Ohio*, and thereafter specialized in the cryptogamous plants. *Musci Alleghanienses* (1845) was followed in 1846 and 1849 by contributions to the *Memoirs* of the American Academy of Sciences "On the Bryology and Hepaticology of North America," and by a valuable addition to Gray's *Manual* on the mosses of the northern United States, published separately in 1856 as *The Musci and Hepaticae of the United States East of the Mississippi River*. In the same year, with the help of Lesquereux, he published *Musci Boreali-Americani Easiccati. Icones Muscorum* (2 vols., 1864-74), containing 129 valuable copper plates, is probably Sullivan's greatest work.

**SULLY, JAMES** (1842-1923). An English psychologist, born at Bridgwater, Somersetshire. He was educated at the Independent College in Taunton, at Regent's Park College, London, and at Göttingen and Berlin. Until 1892 he served as lecturer in the College of Preceptors, London, and in that year became professor of the philosophy of mind and logic in University College, London. He retired in 1903. Sully published both general treatises and special studies in psychology, the most important being: *Sensation and Intuition* (1874); *Illusions* (1881); *Outlines of Psychology* (1884; 4th ed., under the title *Teachers' Handbook of Psychology*, 1903; 5th ed., 1909); *The Human Mind: A Text-Book of Psychology* (1892); *Studies of Childhood* (1895); *Essay on Laughter: Its Forms, its Causes, its Development, and its Value* (1902). He also wrote *Italian Travel Sketches* (1912). Sully became known as one of the most eminent of modern English psychologists; his work carries on the best traditions of the English school, but is characterized by its breadth and by careful recognition of the development of psychological science on the Continent.

**SULLY, JEAN MOUNET.** See MOUNET-SULLY, JEAN.

**SULLY**, su'lê', MAXIMILIEN DE BÉTHUNE, BARON DE ROSNY, DUKE DE (1560-1641). The great Minister of Henry IV of France. He was born at Rosny, near Mantes, the second son of François, Baron de Rosny. He belonged to a Protestant family and was educated with the young Henry at the court of Navarre. This was the beginning of a friendship and a loyal service that continued until Henry's death. He escaped the Massacre of St. Bartholomew, accompanied Henry in his flight from the French court (1576), shared in the campaigns against the Catholic League, distinguishing himself especially at Coutras (1587), and became Henry's best adviser. He urged Henry's acceptance of Catholicism to save the crown. Sully, made Minister of Finance in 1597 and Chief Intendant in 1599, set himself thoroughly to reform the administration. He made a tour through the chief provincial districts, armed with absolute authority, examined the accounts, dealt with delinquents, and replenished the treasury with the wealth he recovered. Sully brought the affairs of the country into order. From 1597 to 1609 he trebled the income of the state. His indefatigable activity was not confined to finance; he practically was in supreme charge of the various other branches of the administration, promoted agriculture, encouraged exports, and constructed roads and bridges. He was made Grand Master of Artillery in 1601, and in 1606 was created Duke de Sully. His service for the King made him disliked by the people for supposed severity. The Catholics hated him for his religion; the Protestants for his refusals to sacrifice the smallest jot of his master's interest for their sake. At Henry's death he was forced to resign his offices and lived in comparative retirement. Sully wrote *Mémoires des sages et royales économies d'état, domestiques, politiques et militaires, de Henri le Grand*, a wearisome work in the form of a narrative addressed to himself by his secretaries. It is through these volumes that we are made acquainted with the great design of Henry for the federation of Europe. The edition in Michaud and Poujoulat, *Nouvelle collection des mémoires pour servir à l'histoire de France*, is from the original. Consult Lavissee, *Sully* (Paris, 1880), and Jean Gauthereau, *Un précurseur financier "Sully"* (Toulouse, 1912), containing a bibliography.

**SULLY, THOMAS** (1783-1872). A portrait painter of the early American school. Born at Horncastle, Lincolnshire, England, he was brought by his parents, who were actors, to Charleston, S. C., in 1792. After a desultory training under a French miniature painter, he removed to New York in 1806, and in 1809 after severe financial difficulties he went to London, where he completed his studies under Benjamin West. After nine months he was compelled through lack of funds to return to America and settled in Philadelphia. In 1837 he again visited England, painting the portrait of Queen Victoria for St. George's Society, Philadelphia. He was one of the best painters of his day, and his portraits display skillful handling and warm mellow color, although they are careless in drawing and often niggling in execution. Among his best-known portraits are those of Commodore Decatur in the City Hall, New York; General Lafayette at Inde-

pendence Hall, and George Frederick Cooke at the Pennsylvania Academy of Fine Arts, Philadelphia; Thomas Jefferson (1821) at the Military Academy, West Point; and portraits of Charles Kemble, Frances Anne Kemble, and Rembrandt Peale, James Madison, Andrew Jackson, and John Marshall, in the Corcoran Gallery, Washington. He is well represented in the Metropolitan Museum, New York, by nine portraits, including those of his wife, daughter, and himself, a charming original sketch of Queen Victoria, and of "Mother and Son." Consult C. H. Hart (ed.), *Register of Portraits Painted by Thomas Sully* (Philadelphia, 1909).

**SULLY-PRUDHOMME**, su'lê'-pru'dôm', RENÉ FRANÇOIS ARMAND (1839-1907). A French poet, born in Paris. He was educated for the law and was a student of science and philosophy. In 1865 he published *Stances et poèmes*, which won praise from Sainte-Beuve for their elegiac sentiment. Encouraged by this he devoted himself to poetry. In 1866 appeared *Les épreuves*, in which the sadness of unbelief is poignantly expressed. *Les solitudes* (1869) and a rhymed translation of the first book of Lucretius (1869) foreshadow by their depth his great philosophical poems *La justice* (1878) and *Le bonheur* (1888). These two poems are among the greatest efforts of French poetry since Victor Hugo and Lamartine. *Impressions de guerre* (1870) deal with some phases of the Franco-German War. *Les destins* (1872), *Vaines tendresses* (1875), and *Le prisme* (1886) are less philosophic and more personal. In 1905 he published *La vraie religion selon Pascal*. Sully-Prudhomme entered the Academy in 1881, and in 1901 received one of the Nobel prizes in recognition of the lofty qualities of his poetry. He devoted a portion of this to establishing an annual award for excellence among the younger French poets. His verses are thoughtful and often melancholy. Open to all impressions, he is reserved in expression.

Walch, *Anthologie des poètes français contemporains* (ib., 1906).

**SULY'S HILL NATIONAL PARK.** See PARK, NATIONAL.

**SULMONA.** See SOLMONA.

**SULPHOCYANIC ACID**, or THIOCYANIC ACID, HCNS. A powerful organic acid analogous in its composition to the well-known cyanic acid (q.v.), HCNO, from which it differs in containing sulphur instead of oxygen. Sulphocyanates, i.e., salts of sulphocyanic acid, may be obtained by the direct action of sulphur on cyanides (i.e., salts of hydrocyanic acid); just as cyanates may be obtained by the direct union of cyanides with oxygen. Thus, potassium sulphocyanate may be obtained by boiling a solution of potassium cyanide with sulphur. Free sulphocyanic acid may be prepared by decomposing barium sulphocyanate with sulphuric acid, and distilling the aqueous acid thus obtained over warm anhydrous chloride of calcium. The acid is thus obtained in the form of a volatile liquid with a characteristic pungent odor. Pure sulphocyanic acid may be preserved for some time if kept cold. At ordinary temperatures it rapidly polymerizes, forming an amorphous yellow substance.

Several sulphocyanates are extensively used as mordants in certain dyeing processes. The principal commercial source of the salts is found in the manufacture of coal gas. The products formed during the destructive distillation of coal include ammonia, cyanogen, a certain amount of ammonium cyanide, and certain compounds of sulphur. In course of the purification of the gas, these by-products are brought into contact with moist ferric oxide to free the gas from sulphur compounds. The sulphur is thus retained partly in the free state, partly as iron sulphide, and by combination with the ammonium cyanide present yields ammonium sulphocyanate, which may be dissolved out of the reacting mixture with water. Ammonium sulphocyanate is usually transformed into the sulphocyanate of copper, from which, in turn, the useful sulphocyanate of barium is obtained by the action of baryta. The sulphocyanate of aluminium, another useful salt of sulphocyanic acid, may be obtained by the action of aluminium sulphate on the sulphocyanate of barium. Most of the sulphocyanates are soluble in water. Sulphocyanate of mercury may be obtained by the action of mercuric nitrate on the sulphocyanate of ammonium. It decomposes on moderate heating, the resulting mass, externally yellow, but black within, assuming a large size and often a fantastic shape. This sulphocyanate is the principal ingredient of the toy known as Pharaoh's serpents. Each serpent consists of a little cone of tinfoil, filled with the salt. On lighting the cone at the apex there begins to issue a thick serpent-like coil, which continues twisting and lengthening to an extraordinary degree. In 1906 Rosanoff and Hill succeeded in working out a reliable method for the quantitative determination of sulphocyanates in the presence of chlorides and bromides.

Like cyanic acid (q.v.), sulphocyanic acid furnishes a simple example of the phenomenon known as tautomerism. The two constitutional formulas corresponding to the acid, as deduced from a study of its two different series of derivatives, are as follows:

The two imaginary compounds corresponding to these formulas, but in reality represented by only one acid, are called, respectively, sulphocyanic acid and isosulphocyanic acid (or thiocyanic acid and isothiocyanic acid).

**SULPHONAL**  $(CH_3)_2C(SO_2C_2H_5)_2$ . A white crystalline compound used as a hypnotic. It is prepared by the action of acetone on mercaptan (q.v.) and the oxidation of the resulting product by permanganate of potassium. Pure sulphonale is a colorless crystalline substance that melts at 125.5° C. (257.9° F.). It is sparingly soluble in water, alcohol, and ether and is best administered with hot milk. It is employed as a substitute for chloral, over which it has the advantage of exercising no depressing action on the heart. It is, however, a poisonous substance and has been known to produce serious functional disturbances and eruptions on the skin. It is sometimes administered in conjunction with trional.

**SULPHOVINIC ACID.** Same as ethyl hydrogen sulphate, or ethyl sulphuric acid.  $C_2H_5.H_2SO_4$ . See ALCOHOL.

**SULPHUR** (Lat. *sulphur*, *sulfur*, sulphur; possibly connected with Ger. *Schwefel*, AS. *swefl*, sulphur). A nonmetallic element, known since ancient times. From the fact that it burns

readily, it was called brennestone or brimstone, and was regarded by the alchemists as the principle of combustibility, representing the alterability of metals by fire. It occurs in the uncombined state, though usually contaminated with clay, bitumen, and other impurities, and sometimes with traces of arsenic, selenium, tellurium, etc., usually in the vicinity of volcanoes and hot springs. The principal localities in which sulphur is mined include the provinces of Caltanissetta and Girgenti in Sicily; Romagna in Italy; the coastal plains of Louisiana and Texas and the Mexican Gulf states; Central Hokkaido in Japan; Caucasus; Upper Egypt; White Island in New Zealand; Iceland, and others. Compounds of sulphur, especially metallic sulphides, are of common occurrence, and include chalcopyrite or copper-iron sulphide, cinnabar or mercury sulphide, galena or lead sulphide, pyrite or iron sulphide, the arsenic sulphides or realgar and orpiment, sphalerite or zinc sulphide, stibnite or antimony sulphide. In combination with metals and oxygen (sulphates), sulphur occurs in such minerals as anglesite or lead sulphate, barite or barium sulphate, celestite or strontium sulphate, chalcantith or copper sulphate, gypsum or calcium sulphate, and kieserite or magnesium sulphate. Volcanic gases generally contain sulphur in the forms of sulphur dioxide and sulphureted hydrogen, and compounds containing it are found in certain organic materials, as the volatile oils of mustard and garlic, hair, wool, bile, and albuminous substances. It is believed that native sulphur has been formed by the action of sulphur dioxide on hydrogen disulphide. Sulphur may also be obtained by decomposing certain mineral sulphides, as pyrite. The commercial article is usually obtained by purifying native sulphur by fusion, or by distillation, and until the close of the nineteenth century was produced largely in Sicily, where it occurs mixed with celestite, gypsum, limestone, and marl, and whence about 16,000,000 tons (probably one-third of the total deposit) have been obtained in the last 300 years. The ore, after being carefully hand-picked, was formerly heated in heaps beneath which the liquid sulphur collected in a trough, whence it was ladled out; but as this process was wasteful, kilns came into use, in which sulphur ore was piled and ignited at the bottom; the heat penetrated it slowly, and as the sulphur gradually melted it ran to the bottom, where it was collected and cast into molds. The crude sulphur obtained in this manner usually contains about 3 per cent of earthy impurities, which may be removed by distillation, in which case the sulphur is first melted and then heated to the boiling point, the vapor of sulphur then passing into a large chamber, where it condenses and falls to the floor in the form of a light yellow crystalline powder commonly known as flowers of sulphur. This is cast into slightly conical wooden molds, when it is known as roll sulphur or brimstone, and sometimes it is allowed to cool in the chamber, when it is obtained in large crystalline masses called block sulphur.

In recent years the sales of Sicilian sulphur, which formerly supplied nearly the entire demand of the world, have been enormously reduced by American competition. In 1902, after several years of ingenious research, Herman Frasch succeeded in developing a most remarkable process for extracting sulphur from deposits like those of Louisiana and Texas, where

the sulphur is covered by many feet of quick-sands and ordinary shaft mining is inapplicable. The Frasch process, which has been generally recognized as a veritable triumph of modern industrial research, consists in introducing superheated water into the sulphur bed; the sulphur melts and is driven to the surface by compressed air. While the principle of Frasch's process is thus quite simple, the engineering difficulties encountered seemed almost insuperable. In present practice, a well, 17 inches in diameter, is bored to a depth of 50 feet; a wrought-iron pipe 13 inches in diameter is sunk within the well, but to a depth often of 250 feet (the top of the sulphur bed); within this a second pipe, 8 inches in diameter and with perforated sides, is sunk to a depth near the bottom of the sulphur bed; within this a third pipe, 6 inches in diameter but with unperforated sides, is sunk to the same depth; through the 8-inch and 6-inch pipes the superheated water is pumped into the sulphur bed; a fourth pipe, 3 inches in diameter and again unperforated, serves to convey the molten sulphur to the surface; finally, a fifth pipe, 1 inch in diameter, unperforated, conveys the compressed air required for driving the molten sulphur upward through the 3-inch pipe. The sulphur thus obtained is 99.95 per cent pure, and the cost of production is exceedingly small.

Sulphur (symbol, S; atomic weight, 32.07) occurs in several allotropic modifications. The commonest, and under ordinary conditions the stablest, of these is a brittle solid that crystallizes in the rhombic system, but that on heating passes into transparent yellowish-brown needles of the monoclinic system. Both of these forms are soluble in carbon disulphide. The modifications of sulphur that are insoluble in carbon disulphide include plastic, amorphous, yellow, and black sulphur. There is a variety of sulphur that is soluble in water. This is known as colloidal sulphur, and is obtained by passing hydrogen disulphide into an aqueous solution of sulphur dioxide. Rhombic sulphur melts at  $114.5^{\circ}\text{C}$ .; monoclinic sulphur melts at  $120^{\circ}\text{C}$ . At  $95.6^{\circ}\text{C}$ . rhombic sulphur begins to change (slowly) into the monoclinic form. Sulphur is a poor conductor of heat and electricity. The element itself is now extensively used in the manufacture of paper from wood pulp and for the prevention of the growth of oidium fungus on grapevines.

Sulphur combines with oxygen to form a dioxide ( $\text{SO}_2$ ) and a trioxide ( $\text{SO}_3$ ), which in turn combine with water to form sulphurous and sulphuric acids ( $\text{H}_2\text{SO}_3$  and  $\text{H}_2\text{SO}_4$  respectively). It also forms a sesquioxide ( $\text{S}_2\text{O}_3$ ) and a heptoxide ( $\text{S}_2\text{O}_7$ ); but these are unimportant. Sulphur dioxide, or sulphurous anhydride, was known to the ancients, and Homer mentions its fumes. It is readily formed by burning sulphur in the air, and also by the action of certain metals, such as copper, on sulphuric acid. It is a colorless gas with a suffocating odor and is freely soluble in water, forming sulphurous acid. Large amounts of it also dissolve in acetone. The gas is used as a bleaching agent, as a disinfectant, and as an antiseptic, serving to prevent the putrefaction of meat and to stop fermentation. It is also used in the sulphuring of wine. Its compound with water, known as sulphurous acid ( $\text{H}_2\text{SO}_3$ ), combines with bases to form a series of salts which are known as sulphites. Sulphur trioxide, or sulphuric anhydride, is formed when a mixture of sulphur dioxide and

oxygen is passed over platinum sponge, or by the distillation of fuming sulphuric acid. It is a colorless mobile liquid that solidifies in the form of long transparent prismatic crystals which melt at  $14.8^{\circ}\text{C}$ . The liquid boils at  $46^{\circ}\text{C}$ . It is very acid and chars paper, wood, and organic matter generally. When thrown into water it dissolves with a hissing sound and evolves a large amount of heat, forming sulphuric acid (q.v.). Under the name of crystallizable sulphuric acid, it is used in the manufacture of coal-tar colors, such as alizarin, and in the purification of ozokerite. With hydrogen and oxygen sulphur forms a series of acids including, besides those already mentioned, the following: thiosulphuric or hyposulphurous acid ( $\text{H}_2\text{S}_2\text{O}_3$ ), which is described elsewhere; hydrosulphurous acid ( $\text{H}_2\text{SO}_2$ ), a powerful reducing agent discovered by Schutzenberger and prepared by the action of metallic zinc on acid sodium sulphite; persulphuric acid ( $\text{H}_2\text{S}_2\text{O}_8$ ), obtained in a combined form by the electrolysis of a strong solution of acid potassium sulphate; pyrosulphurous acid ( $\text{H}_2\text{S}_2\text{O}_5$ ), whose potassium salt is formed when sulphur dioxide gas is passed into a hot aqueous solution of potassium carbonate; pyrosulphuric acid ( $\text{H}_2\text{S}_2\text{O}_7$ ), formed by the direct union of sulphur trioxide and sulphuric acid; dithionic acid ( $\text{H}_2\text{S}_2\text{O}_6$ ), whose manganese salt is formed by the action of sulphur dioxide on manganese dioxide; trithionic acid ( $\text{H}_2\text{S}_3\text{O}_6$ ), whose potassium salt is formed by the action of flowers of sulphur on a warm solution of acid potassium sulphite; tetrathionic acid ( $\text{H}_2\text{S}_4\text{O}_6$ ), whose sodium salt is formed by the action of iodine on sodium hyposulphite; pentathionic acid ( $\text{H}_2\text{S}_5\text{O}_6$ ), formed, along with free sulphur, by the action of sulphur dioxide on aqueous sulphureted hydrogen.

Sulphur combines with hydrogen to form a disulphide (sulphureted hydrogen, q.v.) and a persulphide, of which the former is well known. The persulphide (probably  $\text{H}_2\text{S}_8$ ) is an oily yellow liquid prepared by pouring an aqueous solution of an alkaline polysulphide into excess of a solution of about equal parts of concentrated hydrochloric acid and water. It has the property of bleaching organic coloring matters, and reduces the oxides of gold and silver with great rapidity. With carbon sulphur combines to form a disulphide ( $\text{CS}_2$ ), which is described in a special article. (See CARBON DISULPHIDE.) With chlorine sulphur combines to form a monochloride ( $\text{S}_2\text{Cl}_2$ ), a dichloride ( $\text{SCl}_2$ ), and a tetrachloride ( $\text{SCl}_4$ ), of which the most important is the monochloride. This is prepared by passing dry chlorine gas over melted sulphur and distilling off the chloride from the excess of sulphur. It is an amber-colored liquid that fumes strongly in the air and possesses a penetrating odor. A saturated solution of sulphur in a commercial mixture of the monochloride and the tetrachloride is used in vulcanizing rubber goods. Consult Lucas, "Geology of the Sulphur and Sulphur Oil Deposits of the Coastal Plain," and Pough, "Sulphur Mines of the Union Sulphur Company in Louisiana," in *Journal of Industrial and Engineering Chemistry* (Easton, 1912).

**SULPHUR, MEDICAL USES OF.** Sulphur is used in medicine both internally and externally. It is prepared from crude sulphur by sublimation, washing, and precipitation. Taken by the mouth sulphur in medicinal doses is a mild laxative, producing a soft stool, which slips by

strictures of the rectum, piles, and fissures with little discomfort. It is, therefore, used in these conditions. Sulphur is indicated in chronic rheumatism, either taken in the form of mineral waters containing this element, or externally by means of sulphur baths. The latter are employed in various chronic skin diseases, of obstinate type, such as psoriasis, lichen, and eczema. (See BATH; MINERAL WATERS.) Calcium sulphide is of value in all cases where pus is about to form, as when successive crops of boils appear, and in acne pustulosa.

The external uses of sulphur are mostly confined to affections of the skin and as a parasiticide. It is only active when used in the form of an ointment. For the itch (q.v.) sulphur ointment is a specific. It is also a favorite remedy for ringworm (tinea, q.v.).

**SULPHURET'ED ANTIMONY.** See KERMES MINERAL.

**SULPHURETED HYDROGEN, HYDROGEN SULPHIDE, or HYDROSULPHURIC ACID,  $H_2S$ .** A foul-smelling gaseous acid compound of sulphur and hydrogen, known since the sixteenth century, but first carefully investigated by Scheele in 1777. It occurs uncombined in certain mineral waters and in volcano gases, and is formed in the decomposition of albuminous substances containing sulphur. It also occurs as a product of transformation of gypsum (calcium sulphate) and other metallic sulphates and is a constituent of volcanic exhalations. But whatever its origin, it does not long remain unchanged in the air, being oxidized with great ease. The usual method of preparing the gas consists in causing sulphuric, or preferably hydrochloric, acid to act

gas, somewhat heavier than air; soluble in water and more so in alcohol, the solutions reddening blue litmus paper. Mixed with  $1\frac{1}{2}$  volumes of oxygen and ignited, it explodes, the products of the reaction being water vapor and sulphur dioxide ( $SO_2$ ). With water it forms a hydrate having the formula  $H_2S \cdot 7H_2O$ . Under the influence of cold and pressure sulphureted hydrogen condenses to a colorless mobile liquid. When heated, it dissociates into its component elements, which recombine when the temperature is lowered. Sulphureted hydrogen is very poisonous, and even small proportions of it in the air are dangerous. The presence of free sulphureted hydrogen may be demonstrated by means of a strip of filter paper soaked with a solution of lead acetate, the paper turning brown or black, owing to the formation of lead sulphide. Chlorine and iodine decompose sulphureted hydrogen, and this is why the odor of the latter is readily destroyed by bleaching powder. Sulphureted hydrogen is used in the manufacture of certain metallic sulphides, for the purification of sulphuric acid, and extensively in analytical chemistry. The sulphureted hydrogen produced in certain industrial processes is utilized by burning it and transforming the resulting sulphur dioxide either into sulphuric acid or into free sulphur.

**SULPHURIC ACID,  $H_2SO_4$ .** A well-known acid compound of hydrogen, sulphur, and oxygen. When pure and free from water it is a colorless, oily liquid of specific gravity 1.84 (approximately) at  $0^\circ C$ . While it may readily be undercooled, it solidifies normally at about  $10.5^\circ C$ . ( $50.9^\circ F$ ). At about  $290^\circ C$ . ( $554^\circ F$ ) it

DIAGRAM SHOWING CHAMBER PROCESS FOR MAKING SULPHURIC ACID.

In the figure, A is a bench of pyrites burners, nitre oven, etc. The burner gas is conducted through pipe D to the Glover tower, E, where it meets the dilute acids and oxides of nitrogen. The fan J carries the gases through the pipe I to the first chamber, K, where oxidation of the sulphur dioxide takes place in presence of water vapor supplied by the steam line shown above the chambers, thence to the second and third chambers, M and N, through the flues I<sub>1</sub> and I<sub>2</sub> and surface condensers L and L<sub>1</sub>. The acid drained from the bottom of each chamber and the condensers is collected in the tank R<sub>2</sub>.

The pump S<sub>2</sub> delivers this acid to the tank H<sub>1</sub>, over the Glover tower, or to the storage tank U, whence it goes to the tank car V. The strong acid coming from the Glover tower is collected in cooler Q and tank R<sub>1</sub> and is delivered by the pump S<sub>1</sub> to the tank H<sub>2</sub> over the second Gay-Lussac tower, P, and to the storage tank U<sub>1</sub>. The gases from the last chamber, N, are conducted through the pipe I<sub>3</sub> to the first Gay-Lussac tower, O, and thence to the second Gay-Lussac tower, P, their flow being maintained by the fan J<sub>1</sub>. The exhausted gases pass to the atmosphere at T. The nitrous vitriol from the first Gay-Lussac tower is collected in the tank R<sub>4</sub> and is delivered by the pump S<sub>4</sub> to tank H over the Glover tower. The nitrous vitriol from the second Gay-Lussac tower, containing but little N<sub>2</sub>O<sub>3</sub>, is collected in the tank R<sub>3</sub> and is delivered by the pump S<sub>3</sub> to the tank H<sub>2</sub> over the first Gay-Lussac tower. In different works this scheme varies somewhat in detail but not in its essential points.

on ferrous sulphide. The following rule usually holds good: Sulphureted hydrogen is formed by the action of acids on the sulphides of those metals (e.g., iron, zinc, manganese, calcium, magnesium, sodium, potassium, etc.) which can directly decompose the acids with liberation of hydrogen. Larger quantities of the gas may be prepared by heating sulphur with moistened charcoal or with paraffin, vaseline, or similar substances. Sulphureted hydrogen is a colorless

gas, somewhat heavier than air; soluble in water and more so in alcohol, the solutions reddening blue litmus paper. Mixed with  $1\frac{1}{2}$  volumes of oxygen and ignited, it explodes, the products of the reaction being water vapor and sulphur dioxide ( $SO_2$ ). With water it forms a hydrate having the formula  $H_2S \cdot 7H_2O$ . Under the influence of cold and pressure sulphureted hydrogen condenses to a colorless mobile liquid. When heated, it dissociates into its component elements, which recombine when the temperature is lowered. Sulphureted hydrogen is very poisonous, and even small proportions of it in the air are dangerous. The presence of free sulphureted hydrogen may be demonstrated by means of a strip of filter paper soaked with a solution of lead acetate, the paper turning brown or black, owing to the formation of lead sulphide. Chlorine and iodine decompose sulphureted hydrogen, and this is why the odor of the latter is readily destroyed by bleaching powder. Sulphureted hydrogen is used in the manufacture of certain metallic sulphides, for the purification of sulphuric acid, and extensively in analytical chemistry. The sulphureted hydrogen produced in certain industrial processes is utilized by burning it and transforming the resulting sulphur dioxide either into sulphuric acid or into free sulphur.

of its hydrogen atoms being replaced by metals, with the formation, respectively, of either acid or neutral salts (sulphates). Its chemical constitution is generally assumed to be represented by the formula  $(\text{HO})_2\text{SO}_3$ . By adding to it a little water it may be caused to form the monohydrate  $\text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O}$ , which crystallizes out when the mixture is cooled. Glass bottles containing commercial sulphuric acid often burst in winter, owing to the separation of crystals of this hydrate, whose melting point is about  $8^\circ \text{C}$ . (about  $46^\circ \text{F}$ .), and which decompose into sulphuric acid and water above  $205^\circ \text{C}$ . (about  $370^\circ \text{F}$ .). If pure sulphuric acid is mixed with water in the proportion of 49 parts of the former to 18 parts of the latter, the well-defined dihydrate is formed, having the composition  $\text{H}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$ .

The term "sulphuric acid," however, as technically and commercially understood, seldom if ever refers to the actual monohydrate or to any of the other recognized hydrates of sulphuric acid. It refers either to a series of solutions of the monohydrate in water or to a series of solutions of sulphur trioxide in the monohydrate ( $\text{H}_2\text{SO}_4 + \text{SO}_3$ ). The first series are known commercially as chamber acid ( $50^\circ$ – $55^\circ \text{Be}'$ ), oil of vitriol ( $66^\circ \text{Be}'$ ), and the monohydrate or concentrated acid, containing about 98.5 per cent of  $\text{H}_2\text{SO}_4$ . The second series are termed fuming or Nordhausen acids, and are always estimated alkalimetrically according to the percentage of free sulphur trioxide contained.

Technically, therefore, sulphuric acid might be considered to be the generic name of a series of solutions of sulphur trioxide ( $\text{SO}_3$ ) in water, some of which solutions are distinguished by

involved include the production of sulphur dioxide, the transformation of this into sulphur trioxide, and the transformation of the trioxide into sulphuric acid. Of these, the oxidation of the dioxide is the most important, the dioxide itself being readily produced by burning sulphur, mineral sulphides, or sulphureted hydrogen, with free access of air. The resulting gases, technically termed burner gas, include from 5 to 8 per cent of the dioxide (the remainder consists of the nitrogen and excessive oxygen of the air and impurities). The two processes devised to effect the oxidation of the dioxide are alike catalytic in their action, in so far as the substances used, while producing the required chemical reaction, remain themselves in the end unchanged. These two processes are termed respectively the chamber process and the contact process.

**Chamber Process.** In the chamber process the burner gas is mixed in large lead chambers (and with more or less auxiliary apparatus) with nitric acid, or with the products of the action of sulphuric acid on sodium nitrate. The principal reactions involved, according to Lunge, are as follows:

- (1)  $\text{SO}_2 + \text{NO}_2 + \text{H}_2\text{O} = \text{O} : \text{N}(\text{OH})\text{SO}_3\text{H}$ .
- (2)  $2\text{O} : \text{N}(\text{OH})\text{SO}_3\text{H} + \text{O} = \text{H}_2\text{O} + 2\text{ONOSO}_3\text{H}$ .
- (3)  $2\text{ONOSO}_3\text{H} + \text{H}_2\text{O} = 2\text{SO}_2(\text{OH})_2 + \text{NO} + \text{NO}_2$ .

In addition to the above principal reactions there are further reactions set up in the so-called Gay-Lussac and Glover towers, in which apparatus respectively the catalytic agent is recovered and made available (in the form of nitric acid) for further use. The principle of

DIAGRAM SHOWING CONTACT PROCESS FOR MAKING SULPHURIC ACID.

A is a bench of pyrites burners. The burner gas passes through the flue  $A_1$  to the first cleaning tower, B. Weak sulphuric acid is constantly flowing down this tower, becoming concentrated by the hot burner gas and absorption of the sulphur trioxide contained in the burner gas, and finally flows out at the bottom into the cooler C at a strength of from  $62^\circ$  to  $64^\circ \text{Baumé}$ . From the cooler C the strong acid passes to the tank D and is delivered by the pump  $D_1$  to the storage tank T, or to the tank F over the second cleaning tower, E. A constant stream of strong sulphuric acid from the tank F is kept flowing down this tower. In this tower the burner gas coming from the top of B is further cleaned and dried by the action of the strong acid and then passes to the filter tower, I; the circulation of the gases through the train of apparatus is maintained by the fan J. Before entering the contact oven, the mixed gases are reheated to the proper temperature for the combination of the sulphur dioxide and oxygen in the reheater, K.

The contact oven, L, consists of cast-iron rings with perforated shelves, or diaphragms, upon which is placed the contact mass.

The sulphur trioxide formed in the contact oven now passes through the absorption cylinders,  $M_1, M_2, M_3, M_4$ . These are cylindrical iron tanks connected in such a way that the gas passes from end to end, meeting the weak acid flowing in the opposite direction. Both the gas and the acid in  $M_1$  are richest in sulphur trioxide, while in  $M_4$  the gas and acid are weak. Sulphur trioxide is most readily absorbed by acid containing about 98%  $\text{H}_2\text{SO}_4$ . The strong acid, which is ready for the market as it comes from  $M_1$ , is collected in the tank Q and is delivered by the pump  $Q_1$  to the storage tank R.

The gases coming from the last absorption tank,  $M_4$ , contain still a small amount of unabsorbed sulphur trioxide. In order to recover this, the gases are passed through the tower N, which is supplied with strong acid which absorbs the last traces of sulphur trioxide. The nitrogen and oxygen remaining pass into the air through the pipe O. The tank car S receives acid for shipment from the storage tank, R.

variations of properties which occur uniformly with uniform percentage mixtures of sulphur trioxide and water, most of which are, however, merely solutions of convenient strength for use in the arts.

The manufacture of sulphuric acid is one of the greatest chemical industries. The processes

the chamber process, therefore, is the production of a dilute sulphuric acid by oxidizing (by nitric acid in the presence of water vapor) a burner gas containing say 5 per cent to 8 per cent of sulphur dioxide. During the process there is a reduction of the nitrogen from higher to lower oxides. These latter take up oxygen again and

repeat the cycle in such a way that the nitric acid is practically recovered for further use. This recovery, however, is rarely complete—a certain mechanical loss being unavoidable. The strongest acid which can be produced by the chamber process will correspond to from 50 per cent to 60 per cent of sulphur trioxide. Stronger acids must be produced by driving off the contained water by heat or by isolating the acid by freezing. It is thus possible to produce the concentrated acid (oil of vitriol) of commerce, containing from 93.5 to 97 per cent of pure sulphuric acid; also distilled acid, containing up to 95.5 per cent of  $\text{H}_2\text{SO}_4$ ; but the anhydrous can only be isolated by freezing.

**Contact Process.** In the contact process the method of production is directly synthetical, and acids of any desired strength may be made in one operation. In this process the pyrites burner gas must be first rendered absolutely free from everything other than sulphur dioxide, oxygen, and inert nitrogen, the usual impurities of burner gas, such as dust, moisture, arsenic, selenium, phosphorus, mercury, etc., derived from the raw material used, seriously interfering with the process. After purification, the dry gas is passed through a substance possessing the faculty of causing sulphur dioxide to oxidize into sulphur trioxide, without apparently suffering any change whatever in its own condition. This contact must be brought about under conditions as to temperature according to the substance used. The contact substances used are finely divided platinum in various forms, such as platinized asbestos and pumice, etc., crusts formed of platinum and some soluble sulphate, ferric oxide, cupric sulphate, diatomaceous earth, etc. The transformation of sulphur dioxide into the trioxide takes place best between  $300^\circ$  and  $400^\circ$  C. ( $572^\circ$  to  $752^\circ$  F.). Above  $450^\circ$  C. the transformation grows incomplete, for at that temperature commences the dissociation of sulphur trioxide into dioxide and free oxygen—a dissociation which is complete at  $900^\circ$  C. The formation of sulphur trioxide having been attained, it simply remains either to condense it at the proper temperature in its crystalline condition or to absorb it in sulphuric acid or water until a solution of the required strength is obtained.

**Fuming Sulphuric Acid.** The contact process described above is also used to produce a fuming acid. Fuming acid is generally valued according to the amount of trioxide present, the balance being  $\text{SO}_2(\text{OH})_2$ . If a fuming acid is made by the contact process, the absorption of sulphur trioxide takes place in wrought-iron vessels, upon which free  $\text{SO}_3$  has little action. Cast iron is used for ordinary concentrated sulphuric acid.

The second method, less frequently employed for the manufacture of fuming acid, depends on the action of heat in decomposing some metallic sulphate, with evolution of sulphur trioxide. Sulphate of iron in the form of copperas (ferrous sulphate), and latterly crude ferric sulphate, have been employed. The substance used is heated in clay retorts, and the sulphur trioxide which is expelled is condensed in receivers charged with water, or with oil of vitriol or weak fuming acid. A more recent process is said to be the treatment of sodium pyrosulphate by sulphuric acid, with the following reaction:

The residue of sodium hydrogen sulphate is

heated to  $300^\circ$ – $320^\circ$  C. in a special retort, and reconverted into pyrosulphate.

**History.** Geber was the first to describe sulphuric acid as a spirit which can be produced from alum and which possesses solvent properties. From the year 1613 sulphuric acid was prepared by the apothecaries by burning sulphur with access of air in moist vessels. The birth of the modern method of sulphuric acid making, however, dates from Roebuck's installation of lead chambers in Birmingham in 1746, and his further installation at Prestonpans, in Scotland, in partnership with Garbett. As late, however, as 1800 the Prestonpans works only yielded 111 per cent on the sulphur burned, with a consumption of 13 per cent of nitrate of soda (modern practice would yield 300 per cent of the acid on sulphur burned with a consumption of less than 3 per cent nitrate of soda). The chambers at that time were about 14 feet long, 10 feet high, and 4 feet, 10 inches wide. (They are now commonly 50 feet to 100 feet long, 20 feet to 25 feet high, and 20 feet to 30 feet wide.) In 1827 Gay-Lussac introduced his towers for the recovery of nitric acid. Another important step was the introduction, in 1859, by John Glover, of his denitrating and concentrating tower at the Washington Chemical Works, near Durham, in England. This completed the rational and economical method of manufacture known as "the chamber process." From that time on the history of the chamber process of manufacturing sulphuric acid has been largely one of minor improvements, economics, and investigations into the chemical reactions involved in the process.

In the meantime, however, as early as 1817 the catalytic action of platinum was discovered by Sir Humphry Davy, and this phenomenon was further investigated by Edmund Davy, Döbereiner, and others. In 1831 Peregrine Phillips, Jr., an acetic-acid manufacturer, discovered and patented the application of the catalytic action of platinum to the production of sulphur trioxide. The matter remained dormant until 1848, when the Belgian Schneider claimed to have discovered in pumice stone a substance of great catalytic activity. From this time on the subject received the attention of many scientists in Europe. But it was not until the publication of the investigations of Clemens Winkler in Dingler's *Journal*, in 1875, that the foundation of a commercial contact process can be said to have been securely laid. Subsequent work by Hanisch and Schroeder, Messel and Lunge, and others, followed. Finally, about 1880, the matter was taken up by the Badische Anilin und Soda Fabrik in Germany, and this firm, after a long, costly, and obstinate struggle, brought the process to a commercial success. Other manufacturers also have made the contact process an established success, the different manufacturers working on slightly different methods or different contact materials. As yet, however, the only contact material of demonstrated commercial value is platinum in one or the other form or combination. In the United States the first contact plant was erected in 1899, at Mineral Point, Wis., by the New Jersey Zinc Company under the patents of Schroeder. This plant was almost immediately followed by others, all of which are in successful operation; and while this process cannot be said to have superseded the old chamber process, its advantages are such that its complete triumph is probably only a matter of time and improved methods. E. Thorpe, *Dictionary of Applied Chemistry* (5 vols., London, 1912-13).

**SULPHURIC ETHER.** See ETHER.

**SULPHUROUS, or SULPHUROUS, ACID** ( $\text{H}_2\text{SO}_3$ ). A colorless liquid containing about 6.4 per cent of sulphurous anhydride ( $\text{SO}_2$ ) and 93.6 per cent of water. The gas is a valuable disinfectant and has been used for this purpose from the most ancient times. The gas was formerly employed to disinfect buildings and rooms, although formaldehyde gas is gradually superseding it. See DISINFECTANTS; FUMIGATION.

**SULPHUR SHOWERS.** See POLLINATION.

**SULPHUR SPRINGS.** A city and the county seat of Hopkins Co., Tex., 93 miles east by north of Dallas, and on the St. Louis Southwestern and the Missouri, Kansas, and Texas railroads (Map: Texas, E 3). It has cotton gins, a cotton compress, cottonseed-oil mills, and manufactories of brick and tile, and lumber products. The commission form of government has been adopted. Pop., 1900, 3635; 1910, 5151.

**SULPHUR SPRINGS RESERVATION.** See PARK, NATIONAL, *Platt National Park*.

**SULPICIANs**, sül-pish'anz. A society of priests founded in 1641 by Jean Jacques Olier (q.v.) to educate candidates for the priesthood. It took its name from the parish of Saint-Sulpice in Paris, of which Olier was pastor. When the number of priests had increased beyond the needs of the parish, some took charge of a seminary; and this has since been their principal work. In 1900 they had charge of 26 seminaries in France, but in 1904 the seminary of Paris was taken from them. They came to Canada in 1657 and had a large share in the founding of the city of Montreal as a Christian colony; for a long time they did all the priestly work there, and still conduct the seminary. On the invitation of Bishop Carroll they came to Baltimore in 1791 and founded a seminary there; in 1808 they established another at Emmitsburg, the later Mount St. Mary's College. They also have charge of the seminary in the diocese of San Francisco, and of the clerical students in the Catholic University at Washington.

**SULPICIOUS APOLLINARIS.** A Roman grammarian and learned commentator of the second century, born at Carthage, repeatedly mentioned with high praise by his pupil Aulus Gellius (q.v.). He devoted himself especially to the study of Vergil. Metrical arguments or summaries of the several books of the *Aeneid*, of six hexameters each, and like summaries of the plays of Terence, each in twelve iambic trimeters, written by Apollinaris, are extant. He wrote also *Letters*. Consult: J. W. Beck, *De Sulpicio Apollinari* (Groningen, 1884); M. Schanz, *Geschichte der römischen Literatur*, vol. iii (2d ed., Munich, 1905); W. S. Teuffel, *Geschichte der römischen Literatur*, vol. iii (6th ed., Leipzig, 1913).

**SULPICIOUS** (sül-pish'i-tis) **SEVERUS** (c.363-c.410). An ecclesiastical historian, born in Aquitaine. According to Paulinus (Ep. xxii.) he went to live at Primuliacum, a village near Toulouse, and about this time he seems to have taken monastic vows. He was a friend of St. Martin, Bishop of Tours, whom he frequently

visited, and whose life he wrote (*Vita S. Martini Turonensis*). His biography and his dialogues are of great historical value. The most important of Sulpicius's other writings is his *Historia Sacra*, composed about 403. This book was for a long time used as a textbook for history in the schools of Europe (till c.1656). There is an English version of his writings, by Alexander Roberts, in *Nicene and Post-Nicene Fathers* (vol. xi, 2d series, New York, 1894).

**SULTAN**, sül'tan or sül-tän' (Ar. *sultān*, emperor, empire, from *salita*, to be imperious). A common title of Mohammedan princes since the time of the Ghaznivid Mahmud (997-1030). It is given, par excellence, to the ruler of Turkey, who takes the name "sultan khan," reigning sultan, or sultan of sultans. It is also given to the princesses of the royal house, and the Sultan's mother is called valide sultan; the mother of his first-born son is called hasseki sultan. In English a feminine form, "sultana," is usually employed for women.

**SULTAN**, sül'tan. A breed of small fowls, derived from Turkey, and kept for their beauty of plumage and docility as pets.

A SULTAN COCK.

**SULTE**, sult, BENJAMIN (1841-1923). A French-Canadian author, born at Three Rivers, in the Province of Quebec. Taken from school at the death of his father, who perished at sea, Sulte pushed his way through various employments into journalism and into the service of the government as translator. His most solid prose work is the *Histoire des Canadiens-Français* (8 vols., 1882-84), which was followed by *Histoire de St. François du Lac* (1886) and *Pages d'histoire du Canada* (1891). Sulte is also well known for his songs in *Les Laurentiennes* (1870) and *Les chants nouveaux* (1880). He also wrote *La langue française au Canada* (1898), *Histoire de Québec* (1908), and a number of other publications which appeared in reviews.

**SULU**, sōō-lōō', or JOLÓ. The capital of the island and archipelago of the same name in the Philippines, situated on the northwest coast of the island of Sulu, 99 miles southwest of Zamboanga, Mindanao (Map: Philippine Islands, C 7). The old town, destroyed during the Spanish occupation of 1876-78, was the residence of the sultans from the time of the traditional first leader, Xarib, or Charib, who is reported to have come from Mecca during the latter part of the seventeenth century. The new town, laid out on the hill by the Spaniards at the time of their

permanent occupation, is well constructed and fortified. The harbor is provided with a long stone pier and a lighthouse, and the town is an important shipping place. The population is but a few thousand.

**SULU ARCHIPELAGO.** The southernmost group of the Philippine Islands. It separates the Sulu and Celebes Seas and extends the western extremity of Mindanao southwestward to the northeastern extremity of Borneo (Map: Philippine Islands, C 8). Its combined area is estimated at 1561 square miles. The archipelago consists of several minor groups, each centred around a large island. Of the latter the largest are Basilan and Joló (Sulu) in the north and Tawi-Tawi in the south, whose areas, respectively, are 478, 326, and 232 square miles. The number of islands counted is 425, of which 16 are unnamed rocks. The larger islands are of volcanic formation, and consist of mountains from 1000 to 3000 feet high, with several extinct volcanoes. The mountains are generally surrounded by a coast zone of coral deposits, and most of the smaller islands are wholly of coral formation. The soil is extremely fertile, and the vegetation is luxuriant. The flora is more distinctly related to that of the Philippines, especially Mindanao, than to the Borneo flora; the forests produce the most valuable woods of the east—teak, bamboos, and palms.

Considerable areas in Joló Island are cleared and cultivated, the chief crop being rice, while coffee, cacao, corn, hemp, cotton, and indigo are also raised. The industries include weaving for domestic use, manufactures of cordage and of knives and hatchets, and pearl and shell fishing, the last being commercially important. Trade is almost wholly in the hands of Chinese merchants, and consists chiefly in the exportation of pearl shell to Singapore and Manila and the importation of manufactured goods. The dominant people are the Moros, or Mohammedan Malays, who had invaded and conquered the islands before the arrival of the Europeans. They practice polygamy and a mild form of slavery which the United States government has not abolished, though it has insisted that hereafter no person shall be enslaved. The people are governed directly by local chieftains called *datos*, nominally subject to the Sultan of Sulu. The population of the archipelago is over 121,000. The Sulu Archipelago, with the exception of the Basilan group (501.8 square miles), constitutes the Sulu District of Moro Province, while Basilan is a part of Zamboanga District. The capital of Sulu District is Joló.

When the Sulu Archipelago was discovered by Spanish navigators it was already occupied by the Moros, and formed, together with its possessions in North Borneo, an independent state. The Moros showed a warlike and independent spirit. Spain claimed sovereignty over the islands and their dependencies, but did not exercise it beyond sending occasional punitive expeditions against the pirates, and her sovereignty was disputed by England and Germany. By 1875, however, Spain had gradually gained a foothold and begun to assume actual control. In 1877 traffic was declared free in the archipelago, and Spain abandoned her claim to North Borneo in favor of England. Finally in 1885 England and Germany formally recognized Spanish sovereignty in the islands. It had already been acknowledged by the Sultan in 1878. With the Philippine Islands the Sulu Archipelago

passed into the possession of the United States in 1898. In December, 1899, a treaty was concluded between the Sultan and the United States by which American sovereignty over the islands was recognized. The Sultan was acknowledged and an annual stipend was conferred upon him. The Moros were guaranteed immunity in the practice of their religion. See F. Combés, in *Historia de Mindanao y Joló* (Madrid, 1897), and A. H. S. Landor, *Gems of the East* (New York, 1904).

**SULZER**, *zul'tser*, JOHANN GEORG (1720-79). A Swiss philosopher, born at Winterthur. Educated in Zurich, he went in 1742 to Berlin, where he entertained friendly relations with Euler and Maupertuis, became professor of mathematics at the Joachimsthaler Gymnasium (1747), then at the Ritterakademie (1763), and was elected a member of the Academy. His chief work, in which he sought to reconcile the doctrines of Wolf with the French and English philosophers, is the *Allgemeine Theorie der schonen Kunste* (1771-74; new ed., with literary additions by Blankenburg, 1792-94), supplemented by *Nachtrage, oder Charakteristike der vornehmsten Dichter aller Nationen*, edited by Dyk and Schatz (1792-1808). With Ramler he edited *Kritische Nachrichten aus den Reiche der Gelehrsamkeit* (1750).

**SULZER**, *sul'zer*, WILLIAM (1864- ). An American politician, born in Elizabeth, N. J. He studied at Columbia Law School, was admitted to the bar in 1884, and practiced in New York City. From the outset he was active in Tammany politics. He was a member of the State Assembly from 1889 to 1894, of which he was Speaker in 1893 and minority leader (1892-94). Elected to Congress in 1894 and reelected thereafter successively until 1912, he was an active member of the committee on foreign affairs, championing the cause of the Cuban insurgents, the Boers, and the Russian-American Jews. In 1912 he was elected Governor of New York. He at once advocated radical legislation and proclaimed his independence of machine control. His relations with Charles F. Murphy of Tammany Hall grew steadily less friendly. When he vetoed, as insufficient, the primary law which the Legislature had passed, a conflict developed between him and certain party leaders. Although assailed, he toured the State and called the Legislature in special session to adopt an adequate primary law. Charged with having filed with the Secretary of State a false statement of his receipts and expenditures relative to his campaign fund, he was impeached by the Assembly on this and other charges in 1913. He was tried by the Court for the Trial of Impeachments and was convicted of making a false statement in reference to his campaign fund, although the court found him not guilty of the crime of perjury. The judgment of the court while removing Sulzer from office as Governor also provided that he be not disqualified from holding any other office of honor, trust, or profit under the State. It was widely believed that, even if guilty as charged, he was attacked only because he had refused to obey the machine's commands. He was elected to the State Assembly as a Progressive in the same year. In 1914, after losing the Progressive gubernatorial nomination, he was an Independent candidate, and received without any party support 126,270 votes. He published *Governor Sulzer, the Political Bosses, and the Legislature* (1914).

**SUMACH**, *sū'māk* or *shōō'māk*, or **SUMAC**

(OF. *sumac*, *sumach*, Fr. *sumac*, *sommac*, from Ar. *sumūq*, *sumach*, from *samaqa*, to come of good stock), *Rhus*. A genus of about 120 species of shrubs and small trees of the family Anacardiaceæ, distributed over almost all the world, except its coldest regions. The following species are of commercial importance: Venetian sumach (*Rhus corinus*), known also as wig sumach or wig tree, is a native of southern Europe and western Asia, and is often planted under the name smoke tree as an ornamental shrub. It has simple leaves and hairy corymbs of fruit, which have a sort of resemblance to periwigs. The wood, which dyes yellow, and, with the addition of other substances, green and brown, is known in trade as young fustic. The leaves are astringent, and are used for dyeing Turkey red. The root is also used in dyeing, and the whole plant is used for tanning in Italy. The seed resembles the almond in flavor. *Rhus cotinoides*, a small tree found from Tennessee southward, is very similar to the smoke tree. The very acid fruit of the elm-leaved sumach (*Rhus coriaria*), a native of the Mediterranean region, has been used from the earliest times as a condiment. The Virginian sumach, or staghorn sumach (*Rhus typhina*), is a native of almost all parts of North America, with curiously crooked

STAGHORN SUMACH (*Rhus typhina*).

branches, covered, when young, with a soft velvety down. The staghorn sumach varies from a shrub to a small tree 30 feet high. The smooth-leaved sumach (*Rhus glabra*), a similar species, also North American, is a shrubby plant seldom more than 3 feet high. The collection of the leaves of the sumach, especially *Rhus typhina*, for tanning is an industry in parts of the South. The varnish sumach or Japan varnish tree (*Rhus vernicifera*), a native of Japan and Nepal, yields a varnish much used in Japan for lacquer-work. The expressed oil of the seeds becomes as hard as tallow, and is used for candles. In Australia the wood of *Rhus rhodanthema* (or *Rhodasphera rhodanthema*) is considered one of the most valuable cabinet woods. It is dark yellow with a satiny lustre, and takes an excellent polish. The leaves and bark are used in tanning. The name tanner's sumach is given to *Coriaria myrtifolia*, a European shrub of the family Coriariaceæ.

The leaves are astringent, and are used for tanning and for dyeing black.

The popularly reputed poisonous American species are botanically confused. *Rhus toxicodendron*, a low shrub, is believed to be common only at the South; *Rhus radicans*, the so-called poison oak or ivy, a low, trailing or climbing species, referred by some botanists as a variety of the above species, is more widely distributed. *Rhus vernia*, the so-called poison alder, sumach, dogwood, or swamp sumach, has long been reputed to cause irritation of the skin in some people and to be inert in others, a reputation also pertaining to the preceding species. A saturated alcoholic solution of lead acetate is considered a specific. The fluid extract of Grindellia is similarly employed.

**SUMAROKOV**, *sōō-mā-rō'kōf*, ALEXANDER PETROVITCH (1718-77). A Russian writer of the pseudo-classical period. He was born in Finland, was well educated, entered the military service, became Count Rumiantsev's adjutant, and later reached a high rank. When the first permanent theatre was established at St. Petersburg in 1756 he was made director, and also wrote plays for production at the theatre. Petty of character, quarrelsome, and overambitious, he left the capital, incensed at the insufficient recognition he had received, and began to stage his works at Moscow. After a time he got into disputes with the management of the theatre there, and in despair took to drink, dying in obscurity. Although clumsy and ineffective, his tragedies played an important part in the development of the Russian drama, into which he was the first to introduce the French pseudo-classical theory. His comedies and satires have a great deal of genuine humor and wit, and have influenced considerably Sumarokov's followers. Sumarokov attempted every kind of literary production except the novel. His works were published at Moscow (2d ed., 10 vols., 1787). His best-known drama, *The False Demetrius*, has been rendered into English as *Demetrius the Impostor* (London, 1806).

**SUMATRA**, *sōō-mā'trā*. One of the Sunda Islands, the most westerly, also the largest, not reckoning Borneo, of the Dutch East India Islands, separated from the Malay Peninsula by the Malacca Strait, and from Java by the Sunda Strait (Map: East India Islands, B 5, 6). It extends in a northwest and southeast direction. Its length is 1050 miles; its breadth ranges from 90 to 240 miles. Area, 161,612 square miles.

A high mountain, the Barisan, which widens into three or four parallel ranges, including plateaux, and which is marked by many volcanoes, follows the west shore. To the east, in all the central part, extend lower stretches of level and undulating country sloping eastward, where all the main rivers are found, flowing eastward, often through marshy flats at the coast. The highest elevation, Korintji, 12,480 feet, is in the Residency of Padang in the middle of the island. In the north are plateaux averaging 4000 feet in elevation; next south is a region of extinct volcanoes and deep valleys; in the middle belt are also volcanoes rising to 10,000 feet; the heights diminish in the south but the character of the mountains are not so well known. At least eight active volcanoes exist, and the number of volcanic peaks and craters is large (66 being known).

There are numerous lakes; among the largest are Toba, high up among the northern moun-

tains; Maninju, 50 square miles, in a crater, Singkara, of like size and the source of the Ombilin River and Korintji, near the peak of the same name.

The main rivers are the Musi, Jambi, Indragiri, and Kampar. They are of much importance for navigation. Around a large part of the coast extend rows and groups of islands of more or less significance, and once a portion of the mainland—Banka, Linga, Rupert, Simalu, Siberut, etc. As a whole, Sumatra geologically belongs to the neighboring continental regions; sandstone, limestone, slate, and eruptive formations abound in the island.

The equator passes nearly through the centre of the island; accordingly the even temperature is constantly high, the mean annual temperature ranging from 77° F. to 81° F. The annual rainfall varies from approximately 90 to 185 inches. The lower sections of the island are unhealthy and thinly peopled, the higher are pleasant and habitable. Thunderstorms and waterspouts occur frequently, and earthquakes now and then. The flora is practically that of the Malay Peninsula and Borneo, containing a few remarkable special features, such as gigantic forms of arum. A large part of the island is overgrown with trees and foliage. The mountains are rich in tall timber. Oak, camphor, and teak trees abound. Sumatra is unsurpassed for fauna, nearly all the large equatorial types being present. Buffaloes are the leading live stock. The rhinoceros, elephant, tiger, tapir, panther, deer, and many species of the ape are also largely represented. The supply of minerals is large. The island yields coal abundantly, and large tin deposits on Singkap Island on the east coast are being worked. Petroleum wells flow in the Palembang region, and there is an important output of petroleum in Langkat.

Agriculture is the occupation of the natives. All the tropical crops are or can be grown. The native princes and the government farm out land to cultivators. The natives skillfully manufacture filigree articles in gold and silver, fabrics, and household articles. The northeast coast, around Deli, is a rich and extensive tobacco country. The pepper trade is important. Coffee, bamboo, rubber, copra, and gums are also exported. There are many good roads in various coast districts, and a fair one from Palembang to Benkulen. A railway extends from Padang to coal mines in the interior; altogether there were in operation, in 1912, 337 kilometers (209 miles) of railway.

Java and Madura are the central, civilized, and most important part of the Dutch East Indies, the remainder being known as outposts or outpost provinces. Seven of these outpost provinces are included in Sumatra. So far as is practicable the government is patterned after that of Java, but Dutch control in much of the interior is merely nominal. Besides several Dutch residents there is a governor for the administration of the West Coast and a civil and military governor for Achin (Atjeh). The area of these seven outpost provinces, which include many small islands off the coast, is computed at 178,694 square miles; of Sumatra proper, somewhat less than 167,500 square miles. The most recent available returns of population are for 1905; these, with areas, are shown in the table.

Of the total population in 1905 the number of indigenes was returned at 3,902,107; Chinese, 148,946 (of whom 99,236 in the East Coast);

Europeans, 8190. The principal towns are Padang (with 91,440 inhabitants in 1905), Palembang (60,985), Benkulen, Deli, Achin, and Jambi.

OUTPOST PROVINCES	Sq. miles	Pop., 1905
West Coast:		
Padang Highlands.....	.....	403,431 <sup>1</sup>
Padang Lowlands.....	.....	905,040 <sup>2</sup>
Tapanuli.....	.....	413,301 <sup>3</sup>
Total West Coast.....	31,788	1,721,772 <sup>3</sup>
Benkulen.....	9,437	204,269 <sup>4</sup>
Lampung Districts.....	11,338	156,518 <sup>3</sup>
Palembang.....	53,718	796,354 <sup>3</sup>
East Coast.....	35,481	568,417 <sup>4</sup>
Achin.....	20,550	582,175 <sup>4</sup>

Grand total <sup>2</sup> .....	178,694	4,141,721 <sup>4</sup>

<sup>1</sup> Consists of Indragiri in Sumatra and the Riouw and Lingga archipelagoes.

<sup>2</sup> Including outlying islands except Banka.

<sup>3</sup> Fairly accurate.

<sup>4</sup> Approximate.

The natives of Sumatra, exclusive of the intruding Hindus, Arabs, Tamils, Indo-Chinese, and Chinese, belong to the Malayan stock, linguistically and physically, although some authorities group as Indonesians such peoples as the Battaks and a few others. Among the most important and most interesting tribes are the Achinese of the extreme northwest, noted for their long struggle against the Dutch, the Battaks of the northern interior and northwest coast, and their neighbors in the Nias and Batu islands, the Kubus, a very primitive people of the forests and marshy regions of Palembang, the so-called Menangkabau Malays of the middle of the island and other parts east and west, the Palembang, Rejangs, Passumahs, Lampongs, and other tribes to the south, and the Abongs. The Malayan people of Sumatra exhibit many varieties of culture, from that of the forest-dwelling Kubus and other tribes of a primitive sort to those who under Hindu, and centuries later under Mohammedan, influences reached a considerable degree of culture, with religious and commercial as well as political development and expansion. The first intrusions of Hindu life and culture into Sumatra began some time before the Christian era. Traces of Hinduism are evident in architecture, religion, and language. It was in all probability from Java that Buddhism in the sixth century made its way into Sumatra, where, however, it never obtained general vogue. The Battaks, some of whose divinities bear corrupted Indian names, possess an alphabet of Hindu origin. Hindu influences were probably at their height in the eighth century. From the thirteenth to the fifteenth century Mohammedan influences prevailed and many of the tribes were converted to Islam and a number of sultanates were established. The Mohammedan influence upon politics, religion, and language was great. Since then the various European conquerors and intruders (Portuguese, English, Dutch) have made themselves felt, but chiefly in the coast regions. On the whole the native population of Sumatra, as is also the case in Java, is on the increase. Mohammedanism is generally professed in the coast districts and also to a great extent in the interior.

Marco Polo visited Sumatra in 1292, and the first Portuguese in 1508. In the seventeenth

century the Dutch obtained a firm foothold, having forced out the Portuguese. From 1812 to 1819 the English held the island. In 1825 Benkulen, where the English had been established for nearly a century and a half, was transferred to the Dutch. The conquest of the natives has been in progress since the discovery of the island and has not yet been entirely completed, although almost all of the island is now under the control of the government.

**SUMBA**, sūm'bá, or SANDALWOOD ISLAND (q.v.). One of the Sunda Islands (q.v.).

**SUMBAWA**, sum-bá'wá. An island of the Dutch East Indies, one of the Sunda group, situated between Lombok and Flores (Map: East India Islands, E 7). Its area is 4300 square miles, but including the neighboring islands it is 5240 square miles. Four mountain ranges traverse Sumbawa from west to east, the northern being volcanic with Tambora (9055 feet), the southern containing a limestone formation. Mid-Sumbawa is a region of circular hills of lava and tufa, and the land is covered with a long silver-colored grass. The natives engage in agriculture. Sumbawa, with its four free states, is included, for the administrative purposes of the Dutch, under Residency No. XI of Insulinde or Island India (government of southern Celebes). The population is 75,000, of which 11,000 are foreigners, who control the trade.

**SUMBUL**, sūm'būl or sum'būl. See MUSK PLANT.

**SUM'DUM'** (or **HOLKHAM**) BAY. One of the most remarkable of the glacial fiords of southeast Alaska, situated about lat. 57° 30' N., long. 133° W., and debouches into Stephens Passage (Map: Alaska, N 7).

**SUMENEP**. See MADURA.

**SUMERIAN LANGUAGE**. The language spoken by the Sumerians. (See BABYLONIA.) The first successful decipherers of the cuneiform characters, Hincks, Rawlinson, and Oppert, observed that the wedge-shaped signs were employed in writing languages not akin to the Assyrian, that the inventors of this system of writing cannot have been Semites, since the signs have syllabic values and some characteristic Semitic sounds are not represented, and that one of these languages was used in Babylonia itself. Hincks thought that these languages were Aryan; Rawlinson regarded them as Scythian, meaning by this term Mongolian; Oppert considered the Babylonian non-Semitic tongue as Kasdo-Scythian. The term "Accadian" was first used by Rawlinson in 1855, the term "Sumerian" by Oppert in 1869. There was practical unanimity among all Assyriologists before 1874 as to the agglutinating and non-Semitic character of this

language. In that year, however, Halévy began his protest against the very assumption that the Sumerian language ever existed. He first attempted to prove that the Sumerian language did not belong to the Turanian family and that the Turanian people cannot be supposed to have lived in Babylonia, and then maintained that the texts claimed to be Sumerian could be regarded as composed in an ideographic writing invented by the Assyrians in addition to the phonetic system and having the same values in pronunciation. Of the Sumerian signs in the syllabary, he found Semitic values for 114. In 1876 Halévy modified his view by admitting that the Sumerian signs could not have been pronounced like the ordinary Assyrian words. In his opinion the so-called Sumerian was only a hieratic or priestly system of writing used as a cryptography for purposes of concealment. Against this theory especially Oppert and Lenormant, Sayce, and Schrader urged many arguments, such as the impossibility of finding real Semitic values for the Sumerian signs and the improbability of an artificial language having been created as a secret means of communication between priests and then used for inscriptions in which kings recount their victories and their building enterprises. In 1880 Haupt indicated the existence of two dialects, Emeku and Emesal, of the Sumerian as shown by certain differences observed by earlier scholars without full appreciation of their significance. Even in view of this fact, explained by Halévy as due to varieties of cryptography, the difficulty of classifying the Sumerian, the apparent silence of the monuments concerning a nation speaking this language and conquered by the Babylonians, and the manifest influence of the Semitic speech on the vocabulary, led some scholars to hesitate. Meanwhile the study of the Sumerian, on the assumption that it was a real language, continued. Lehmann's investigations rendered it probable that the native name of the people speaking this language was Shumeri, in distinction from the Akkadi, who were the Semites. The Semitic language is indeed designated as Akkadian in contrast with the Sumerian in an inscription from the reign of Samsuditava (1963-32 B.C.), as Messerschmidt has shown (*Orientalistische Literaturzeitung*, Leipzig, 1905). In view of the Greek transcriptions of Sumerian words, published and discussed by Pinches and Sayce in 1902, it is no longer possible to doubt the existence of a Sumerian language; but these texts raise the question whether Hellenistic settlers in Babylonia between 146 and 80 B.C., the date assigned by Sayce, were learning an absolutely dead language for historical purposes or a tongue to some extent still spoken. Lehmann's opinion that the home of the Akkadians was in north Babylonia, that of the Sumerians in south Babylonia, which was still adhered to by King in 1910, may have to be modified in the light of the texts published by Scheil in 1911, showing that the earliest Sumerian dynasties, those of Opis and Kish, were north Babylonian.

The Sumerian is found in bilingual syllabaries and word lists, bilingual hymns and prayers, bilingual inscriptions of kings, and a constantly increasing number of unilingual inscriptions. Of these the earliest show the least evidence of a Semitic influence. These are in the Emeku dialect. Those in the Emesal dialect naturally reveal more traces of the Semitic vernacular. Sumerian loan words in the Akkadian, of which

Leander has counted 217, are taken from the Emeku dialect. The Sumerian is made up of monosyllabic roots and shows no tendency to trilateralism; it is fond of compounds, which are rarely found in the Semitic languages, and expands its nouns by many prefixes and suffixes; it has no gender. The plural is often formed by duplication, as *kur-kur* (lands), *si-si* (horns), and sometimes by *ini*; the genitive is sometimes expressed by the suffix *ge* or *gid*; instead of prepositions it has postpositions, such as *-shu*, to, *-ta*, from, *-da*, with; the pronouns are either independent or pronominal suffixes, but altogether different from the Semitic; the numerals resemble the Semitic only in making the twenties, thirties, etc., in the plural, while the forms are entirely different; the verb has practically the same derived stems as the Semitic and Hamitic, but has a greater variety of prefixes, infixes, and suffixes. The attempts to discover the affinities of this language have not yet been successful, but it is probably the oldest known language in the world; it has an *e* vowel and an *o* vowel and also a consonant *f*, as the Greek transcriptions show. From the Sumerian vocabulary it is evident that the people who spoke this language had reached a comparatively high civilization. The sexagesimal system was in vogue, and the beginnings of astronomy and mathematics are with much plausibility ascribed to the race who spoke the *Ushan Shumeri* or Sumerian language.

See CUNEIFORM INSCRIPTIONS.

**SUMERIANS.** See SUMERIAN LANGUAGE; BABYLONIA, *Ethnology*.

**SUMIDA-GAWA**, sūō'mé-dā-gū'wā. A river in the island of Hondo, Japan, rising northwest of Tokyo on the border of the provinces of Musashi and Kai, and entering the Bay of Tokyo, after a course of some 90 miles. It is navigable for small boats. In Tokyo it is a place of popular resort. On its banks are tea houses, temples, and a great avenue of cherry trees. In July it is the scene of a great festival called "river opening."

**SUMMARY PROCEEDINGS** (from Lat.

*summa*, main thing, substance, sum, fem. sing. of *summus*, superlative assigned to *super*, above, over). Proceedings in the nature of trials which are conducted before judicial officers without juries, and in a speedy and peremptory manner. Such proceedings must be specially authorized by statute, as they are not sanctioned by the common law. The Federal constitutional guaranty of the right to trial by jury does not extend to such civil and criminal cases as were not triable by jury at common law, thus leaving the States free to dispose of such cases by summary proceedings if they deem it expedient to do so. Most of the State constitutions also secure the right to trial by jury in all important cases. However, for the speedy administration of justice in trivial cases, both civil and criminal, the statutes of nearly all the States provide for the determination by summary proceedings of such petty misdemeanors as the violation of municipal ordinances as to fast driving, etc., disorderly conduct, and other minor offenses.

Certain statutory proceedings for the purpose of promptly ejecting or dispossessing tenants are also known as summary proceedings in some States. See JURY; TRIAL.

**SUMMER.** A term, found in old English architecture, applying to a chief beam of a floor, or what is ordinarily termed a girder. When a summer is used to support a wall or other superstructure, as in the front of a building, it is known as a breastsummer (q.v.). Summer is also used to denote a stone at the top of a pier or of a wall where an arch, lintel, or other work is supported.

**SUMMER, INDIAN.** See INDIAN SUMMER.

**SUMMER DUCK.** The wood duck (q.v.).

**SUMMERFIELD, JOHN** (1798-1825). An American Methodist clergyman, born at Preston, England. He was educated at a Moravian school. In 1812 his family removed to Dublin. Here he became dissolute and was finally imprisoned as the result of indorsing the notes of worthless companions. Converted in 1817, he joined the Wesleyans and in 1819 was preaching to immense audiences in Dublin. In 1821 he came to the United States and entered the ministry of the Methodist Episcopal church, joining the New York Conference. He was greeted with enthusiastic crowds wherever he spoke. A short time before his death he was instrumental in founding the American Tract Society. He was the author of *Sermons and Sketches of Sermons* (1842). Consult John Holland, *Memoirs of the Life and Ministry of Rev. John Summerfield* (New York, 1829; 6th ed., 1844); W. M. Willett, *The Life of Rev. John Summerfield* (Philadelphia, 1857).

**SUMMER REDBIRD**, or **TANAGER.** See TANAGER.

**SUMMERS, SIR GEORGE.** See SOMERS, SIR GEORGE.

**SUMMERS, THOMAS OSMUND** (1812-82). An American Southern Methodist clergyman, editor, and theologian. He was born at Corfe Castle, Isle of Purbeck, Dorsetshire, came to America in 1830, and joined the Baltimore Conference (1835). He was missionary to the Republic of Texas (1840); was transferred to the Alabama Conference (1843); was secretary of the Louisville convention where the Methodist Episcopal Church South was organized; and subsequently was secretary of every General Conference of his church until his death. As

general book editor from 1845 until his death, he edited most of the publications of the denomination. He founded the *Sunday School Visitor* and edited it for four years; the *Quarterly Review* he edited for nine years. Summers was professor of systematic theology in Vanderbilt University and dean of the theological faculty (1872-82). He wrote numerous works, including a commentary in six volumes on the Gospels, Acts, and Romans (1868-74) and *Systematic Theology*, edited by J. J. Tigert (2 vols., 1888). Consult O. P. Fitzgerald, *Dr. Summers: A Life Study* (Nashville, 1884).

**SUMMERS, WALTER COVENTRY** (1869- ). An English classical scholar. He was educated at St. John's College, Cambridge, and was lecturer in Latin at Owens College, Manchester (1895-1903), and thereafter was professor of Latin at the University of Sheffield. His publications include: editions of Sallust (1900, 1901), Ovid (1902), Tacitus (1904), and of Selected Letters of Seneca (1910); *A Study of the Argonautica of Valerius Flaccus* (1894); texts of Persius and Silius Italicus in the *Corpus Poetarum Latinorum* (1900-04); *The Authorship of the Hercules Oetaeus* (1905); and the discussion of "Silver Poetry" in J. E. Sandys's *Companion to Latin Studies* (1910).

**SUMMER SCHOOL.** The name applied either to institutions the sole purpose of which is the giving of instruction during the summer months, or to the summer sessions of any institution of learning. Some universities in the United States offer courses extending over a part of the summer, and a few, like the University of Chicago, have regular summer quarters as part of the system of continuous sessions. The successful completion of summer-school courses gives credit towards the degrees of the institution at which they are taken. Other summer schools exist independently, usually at some situation favorable for summer resort. Such are the schools at Chautauqua, N. Y. Conditions of admission are usually not required. Certificates are given for work done. More recently city-school systems have introduced vacation schools in the summer, chiefly for backward pupils and for physical culture.

**SUMMERSIDE.** A town and the county seat of Prince County, Prince Edward Island, Canada, situated on Northumberland Strait and on the Prince Edward Island Railway (Map: New Brunswick). It is a centre of the fox-ranching industry and has an export trade in oysters and lobsters. Pop., 1901, 2875; 1911, 2678.

**SUMMERSON, ESTHER.** The heroine of Dickens's *Bleak House*.

**SUMMERVILLE.** A city in Richmond Co., Ga., adjoining Augusta on the northwest, on the Central of Georgia Railroad. It is a residential suburb of Augusta and a winter resort. A United States arsenal situated here is the headquarters of the Ordnance Department of the Gulf. Pop., 1900, 3245; 1910, 4361.

**SUMMER YELLOWBIRD.** See **WARBLER**.

**SUMMIT.** A city in Union Co., N. J., situated on the top of the Orange Mountains, 12 miles west of Newark, on the Delaware, Lackawanna, and Western and the Rahway Valley railroads (Map: New Jersey, D 2). It is attractive because of its elevation and the natural beauty of its scenery. It has a public library, the Overlook Hospital, and many fine suburban homes. There is a silk factory with 400 hands.

Pop., 1900, 5302; 1910, 7500; 1915 (State census), 9136; 1920, 10,174.

**SUMMONS** (OF. *semonse*, Fr. *semonce*, summons, admonition). A writ or process by which a defendant is notified to appear in court and answer the cause of action alleged in the plaintiff's complaint or declaration. It has superseded the *original writs* for the purpose of beginning an action in England and in most of the United States. In the absence of statutory provisions to the contrary, a summons must be signed by the clerk of the court in which the action is brought, but under the codes it is usually signed by the plaintiff's attorney. See **PROCEDURE**; **SERVICE OF PAPERS AND PROCESS**; **WRIT**.

**SUM'MUM BO'NUM.** See **ETHICS**.

**SUMNER, CHARLES** (1811-74). An American statesman. He was born in Boston, Jan. 6, 1811, graduated at Harvard in 1830; entered the Harvard Law School the following year, and was admitted to the bar in 1834. In early life he maintained unusual literary activity, writing chiefly upon legal topics, and appearing as a lecturer. His strength becoming overtaxed from literary labor, he sailed for Europe in 1837, traveling for three years, devoting much time to languages, literature, and history. Returning to America in 1840, he began to take an active interest in the antislavery movement, and in 1845 he delivered a notable Fourth of July oration at Boston, on "The True Grandeur of Nations." This gave offense to prominent Whigs and led eventually to his withdrawal from their party. This oration was soon followed by others of great force, mainly against slavery. He was a leader of the "Conscience Whigs" of Massachusetts, who helped to form the Free Soil party. In 1851, through a combination of Free Soilers and Democrats, he was elected to the United States Senate, of which body he was a member until his death. Here he waged an uncompromising war on slavery. His first important speech (August, 1852) was entitled "Freedom National; Slavery Sectional." This was followed in 1856 by another on "The Crime against Kansas," in which he reflected severely upon Senator Butler of South Carolina. This arraignment led to an assault in the Senate Chamber upon Sumner by Preston Brooks (q.v.), a Southern Representative and a relative of Butler, Sumner being so injured that he was incapacitated for nearly four years. This attack led to the disease which ended his life. In December, 1859, he resumed his seat, but took little part in the debates until the middle of 1860, when he delivered a speech on "The Barbarism of Slavery." From the beginning he was recognized as one of the leading men in the Republican party. In 1861 he became chairman of the Senate Committee on Foreign Relations, and made a number of able speeches on questions of foreign concern during the war, notably on the Trent Affair (q.v.).

For ten years of a critical period Sumner held this chairmanship. He took an active part in the debates on reconstruction and allied questions, ably advocating what came to be known as the "suicide theory" of the status of the Southern States at the close of the war. He favored negro suffrage, since he believed the negro could only be protected by giving him the ballot. (See **RECONSTRUCTION**.) He supported impeachment proceedings against President Johnson and secured the enactment of a civil

rights law to secure equality of treatment to negroes in public places, subsequently declared unconstitutional by the Supreme Court. He broke with the Grant administration on the question of the annexation of Santo Domingo, and in 1872 joined the Liberal-Republican movement in advocating the election of Greeley for President. Sumner was a pioneer in civil service reform, and in 1864 introduced such a bill in the Senate. Sumner's *Works* were published in 15 volumes (Boston, 1874-83). Consult: E. L. Pierce, *Memoir* (4 vols., Boston, 1877-93); Moorfield Storey, *Charles Sumner*, in the "American Statesmen Series" (ib., 1900); G. H. Haynes, *Charles Sumner* (New York, 1909); W. G. Shotwell, *Life of Charles Sumner* (ib., 1910); Gamaliel Bradford, *Union Portraits* (Boston, 1916).

**SUMNER, EDWIN VOSE** (1797-1863). An American soldier, born in Boston, Mass. He was educated at Milton Academy, entered the United States army, serving in the Black Hawk War, and on the Western frontier. In 1838 he took charge of the school of cavalry practice at Carlisle Barracks, Pa. In the Mexican War, having attained the rank of major, he participated in all engagements of Scott's army from Vera Cruz to the city of Mexico, was wounded at Cerro Gordo, and for gallantry in holding in check a body of 5000 Mexican lancers at Molino del Rey was brevetted colonel. In March, 1861, he was promoted to the rank of brigadier general, and relieved Albert Sidney Johnston (q.v.) of the command of the Department of the Pacific. In the following year he was recalled and placed in command of the First Corps of the Army of the Potomac. He distinguished himself in the Peninsular campaign, particularly at Seven Pines (q.v.); was twice wounded in the Seven Days' Battles; was brevetted major general in the regular army and was appointed major general of volunteers; and took part at Antietam, where he was again wounded. He commanded the right wing of Burnside's army at Fredericksburg. Relieved at his own request after the appointment of Hooker to succeed Burnside, he was assigned to the command of the Department of Missouri, and died suddenly while on his way thither.

**SUMNER, INCREASE** (1746-99). An American jurist, born at Roxbury, Mass. He was educated at Harvard, where he graduated in 1767, and studied law in the office of Samuel Adams. He was admitted to the bar in 1770, and he was a member of the State Constitutional Convention of 1779. In 1782 he was elected to Congress, but at the same time was offered an associate justiceship of the Supreme Court, which he held till 1797. In 1789 he was a member of the convention which adopted the Constitution of the United States. In 1797 he was elected Governor of Massachusetts, and held that office during the remainder of his life.

**SUMNER, WILLIAM GRAHAM** (1840-1910). An American economist, born at Paterson, N. J. He graduated at Yale in 1863, studied at Göttingen and Oxford, and was tutor at Yale in 1866-69. Ordained in the Protestant Episcopal church in 1867, for some time he was assistant at Calvary Church, New York, and rector at Morristown, N. J. After 1872 he was professor of political and social science at Yale. His pungent and incisive advocacy of free trade attracted wide notice. Among his writings are: *History of American Currency* (1874); *Lectures*

*on the History of Protection in the United States* (1875); *Life of Andrew Jackson* ("American Statesmen Series") (1882); *What Social Classes Owe to Each Other* (1882); *Essays in Political and Social Sciences* (1883); *Protectionism* (1885); *Robert Morris* (1891); *The Financier and Finances of the American Revolution* (1892); *A History of Banking in the United States* (1896); *Folkways* (1907). Posthumously published were *Earth-Hunger and Other Essays* (1913) and *The Challenge of Facts and other Essays* (1914).

**SUMNER METHOD.** See NAVIGATION.

**SUMO, sūmō.** A Central American tribe. See ULUA.

**SUMPTUARY LAWS** (Lat. *sumptuarius*, relating to expenditure, from *sumptus*, expenditure, expense). Laws to prevent extravagance in private expenditure, and indirectly to prevent immorality and crime. The purpose of sumptuary legislation may be grouped under the following heads: (1) To prevent poverty and diminish the cost of supporting the poor; (2) to increase the possible revenue of the state by diminishing private expenditure; (3) to prevent luxury when considered an evil; (4) to favor certain commercial or political interests; (5) to enforce class distinctions; (6) to prevent the consumption of commodities, as liquors and tobacco, which are considered dangerous to health and morals. Sumptuary laws were common in ancient legislation. By means of them Greece endeavored to inculcate simple habits of life among her people. Women, except prostitutes, were forbidden to wear expensive attire, as gold or embroidered apparel. The laws of Solon forbade costly banquets and funerals. At an early period in Roman history the censors, to whom was intrusted the superintendence of public and private morality, punished all persons guilty of luxurious living; but as the love of luxury grew with the increase of wealth and foreign conquest, various legislative enactments were passed with the object of restraining it. The Twelve Tables limited expenditures for funerals. Other early laws of Rome limited the expenditures of women, specified the number of guests at an entertainment, etc.

Sumptuary laws found favor in England from the time of Edward III down to the Reformation. In the reign of Edward III one act prohibited more than two courses at a meal or more than two kinds of food at a course, except in the principal festivals. Another act prescribed the kinds of clothing the various classes might wear, except for the nobility above the knights.

When the mercantilistic theories of government emerged nations endeavored to control consumption by prohibiting the use of commodities produced abroad. It was held that the luxury of a people enriched other nations and impoverished their own. An English law prohibited the wearing of silk in order to encourage the manufacture of woolen goods in England. In France a law at one time prohibited the wearing of gold and silver embroidery, silks, and fine linens.

Aside from protectionism sumptuary legislation to-day comes under the head of police regulations and is aimed to preserve the public health and morals. Under the United States Federal and State constitutions no restriction can be placed on the consumption of commodities or traffic in them, save as the public health, protection, and safety require it. The chief restrictive legislation is directed against the traf-

fic in intoxicating drinks. Consult: W. Denton, *England in the Fifteenth Century* (London, 1888); W. J. Ashley, *Introduction to English Economic History and Theory* (2 vols., New York, 1893); William Cunningham, *Outlines of English Industrial History* (3d ed., Cambridge, 1904).

**SUMTER.** A city and the county seat of Sumter Co., S. C., 43 miles by rail east by south of Columbia, on the Atlantic Coast Line, the Carolina, Atlantic, and Western, and the Southern railroads (Map: South Carolina, D 3). It is known for its large trade in cotton. There are a cotton compress, cotton and cottonseed-oil mills, lumber mills, telephone, magneto, buggy, shoe and building-supply factories, a foundry and machine shop, tobacco flue shops, coffin and casket factories, and a manufactory of golf sticks. Noteworthy features are the St. Joseph's Academy for Girls and the Y. M. C. A. The commission form of government was adopted in 1913. Pop., 1900, 5673; 1910, 8109; 1915 (U. S. est.), 9392.

**SUMTER, FORT.** See FORT SUMTER.

**SUMTER, THOMAS** (1734-1832). An American soldier, born in Hanover Co., Va. He early removed to South Carolina; fought against the Cherokees; served under Braddock in 1755, and in March, 1776, became lieutenant colonel of the Second Regiment of South Carolina Riflemen. Until the capture of Charleston (1780), he served in the interior of the State against the Loyalists and Indians; but subsequently raised a regiment in North Carolina and engaged actively in partisan warfare. On July 12, 1780, he defeated a force of mounted infantry under Captain Huck, and soon afterward was made a brigadier general of State troops. On August 1st he made a spirited but unsuccessful attack on Rocky Mount, and on August 6th defeated 500 regulars and Tories at Hanging Rock, but was subsequently driven back. He then cut Cornwallis' line of communications between Charleston and Camden, capturing a supply train; but later his force was almost annihilated by Tarleton at Fishing Creek. Enlisting another regiment, he defeated Major Wemys at Broad River (November 9th), and on November 20th repulsed an attack of Tarleton at Blackstock Hill, with great loss to the latter. Here Sumter was severely wounded, but he returned in February, 1781, and continued to render efficient service as a partisan commander. After the war Sumter sat in the State convention of South Carolina which ratified the Federal Constitution, was a member of Congress in 1789-93 and 1797-1801, and of the United States Senate from 1801 to 1809 and again from 1811 to 1817, and was United States Minister to Brazil in 1809-11. He was the last surviving general officer of the Revolution. Consult E. McCrady, *The History of South Carolina in the Revolution*, 2 vols. (New York, 1901-02).

**SUMY, со́мь.** The capital of a district in the Government of Kharkov, Russia, situated 125 miles northwest of Kharkov (Map: Russia, D 4). Its chief manufactures are machinery, tobacco, and liqueurs. Pop., 1911, 51,545.

**SUN** (AS. *sunne*, Ger. *Sonne*; connected with AS. *sol*, Lat. *sol*, sun). The central governing body of the solar system (q.v.), and the chief source of light and heat. To us the sun is the most important of all the heavenly bodies, since upon it depends life on the earth. The sun's apparent angular diameter is 32'.0"; diameter in

miles, 865,000; density, 1.41, water being 1; mean distance from the earth, 92,930,000 miles. The sun's distance from the earth is the fundamental unit of linear measures in cosmic astronomy. The method of the determination of this distance is given under PARALLAX.

Successive generations of astronomers have been able to gather much information as to the appearance, constitution, and structure of the sun. The theory at present accepted is as follows: The visible light-giving surface, as we see it in the telescope, is called the photosphere. It may be a collection of luminous clouds, holding in suspension certain particles condensed out of the extremely hot gaseous material of which the innermost nucleus of the sun is probably composed; or it may be purely gaseous, under sufficient pressure to yield a continuous spectrum. Just outside the photosphere is a thin shell of gaseous matter called the reversing layer, composed of many substances such as we find among the known chemical elements of our earth. It is observed, and its existence demonstrated, by the spectroscope. According to Kirchhoff's theory, when light coming from incandescent solids or liquids (or gases under pressure) is passed through vaporized matter, the vapors absorb or cut off the light from certain definite parts of the spectrum. To each vaporized substance belongs its own series of such points in the spectrum; and these correspond exactly to the positions which would be occupied by bright lines in a spectrum derived directly from such vaporized substances themselves, if rendered incandescent. Thus the ordinary solar spectrum is crossed by certain well-known dark lines corresponding to the absorption of certain parts of the photospheric light by the vapors of the reversing layer. Now if it were possible to get rid of the light of the photosphere and examine directly the light of the reversing layer, we ought to see the spectrum of ordinary incandescent gases. This observation can actually be made at the time of a total solar eclipse. If we watch the solar spectrum very carefully just before the beginning of totality, when the moon's advancing edge is on the point of obscuring the sun completely, there will come a moment when nothing remains in sight but the gases of the reversing layer. At that instant the dark lines in the spectrum are suddenly reversed, becoming bright like the lines in the spectrum of a gas heated to incandescence artificially in the laboratory. This remarkable observation was made by Young (q.v.) at the Spanish eclipse of 1870, and repeated photographically at many subsequent eclipses. All of these bright lines can now be photographed on any clear day of good definition with the powerful spectrograph and tower telescope of the Mount Wilson solar observatory (q.v.).

The chemical constitution of the sun has been studied with great care spectroscopically. The spectroscope, when suitably arranged for the purpose, enables us to compare solar light with light obtained in the laboratory from vapors of terrestrial substances raised to incandescence by artificial heating. In this way many terrestrial chemical elements have been identified in the sun; in fact, if the earth were heated to the temperature of the sun it would give a very similar spectrum. This is a fact of importance in its bearing on the origin and evolution of the solar system. See NEBULÆ; COSMOGONY.

The most conspicuous phenomena of the solar surface are the sun spots (Fig. 1). These resemble great holes or depressions in the photospheric surface, usually having a dark spot in the middle surrounded by a sort of radial grating. They vary in diameter from 500 to 30,000 miles for the central dark part (umbra) and range up to 100,000 miles or more for the surrounding less dusky portions. At times they are large enough to be seen with the naked eye. The faculae are bright streaks seen in various parts of the photospheric surface, but usually near spots, and most conspicuous when approaching the edge of the solar disk. The spots usually begin as mere dots, and then grow gradually or rapidly to the enormous dimensions already stated. At times they break into several pieces, giving rise to a group or collection of several spots. They are by no means immovable upon the solar surface, but have more or less irregular motions of their own, those near the sun's equator traveling (on the average) farther from the poles, and those in higher solar latitudes increasing their distance from the equator. But sun spots are rarely found farther from the solar equator than lat.  $45^\circ$ , and few are nearer the equator than lat.  $5^\circ$ . One of the most remarkable things about the spots is the fact that their frequency is periodic. Once in about 11 years they have a maximum frequency, and astronomers are able to record their occurrence in greater numbers than usual. The cause of this periodicity is unknown.

The so-called chromosphere is a great layer composed of very hot gases, principally hydrogen, helium, and calcium vapor, surrounding the sun chiefly outside the reversing layer, which may be regarded as its lower portion. It is supposed, however, that both these strata are mixed together, except that the hottest and densest gases are in the lower or reversing layer. This chromospheric layer can be seen for an instant at the beginning or end of a total solar eclipse, and it is found to consist principally of a mass of red flames. The color is due to the preponderating presence of hydrogen, and it is this color that gives rise to the name chromosphere or colorsphere. The presence of flame does not, however, indicate a process of combustion in the usual sense of the word. For instance, coal burning in an ordinary stove is really being combined chemically with the oxygen of the air, and chemical combination of that character is certainly not going on in the sun.

The most interesting features of the chromosphere are the prominences. These are great eruptive jets of luminous hydrogen, helium, and calcium vapor rising from the solar surface, sometimes to a distance of hundreds of thousands of miles into space. They were first seen during total solar eclipses, when the bright light of the central solar disk had been obscured by the interposed moon. Under ordinary circumstances the central solar light illuminates our terrestrial atmosphere very strongly, and enough of this light is reflected from the air itself into our telescopes to mask completely the fainter light of the prominences. But it has been found possible to study the prominences spectroscopically during full sunlight, and without waiting for a solar eclipse. This was first done visually in 1868 by Janssen, Lockyer (q.v.), and Huggins (q.v.), and photographically by Hale (q.v.) in 1892 and Deslandres in 1894. The two latter

astronomers working independently of each other, the former in Chicago and the latter in Paris, devised certain instruments called spectroheliographs, by means of which it is possible to take pictures of the chromosphere and prominences over the entire solar circumference at once and in full sunlight (Fig. 2). It has been learned from observations with the spectroscope and spectroheliograph that the velocity of motion in eruptive prominences may be as great as several hundred miles per second, indicating real explosions of incalculable force. But many of the prominences are cloudlike or quiescent, and change slowly in form. Fig. 3 represents a quiescent prominence about 80,000 miles high, photographed with the spectroheliograph on Mount Wilson.

Besides recording photographically the chromosphere and prominences on the sun's circumference, the spectroheliograph has opened to investigation the solar atmosphere in projection against the disk. Thus, while a direct photograph of the sun shows only the spots (Fig. 1) and occasionally a few bright faculae near the circumference, a spectroheliogram reveals extensive bright clouds of calcium vapor (the *floculi*) in the solar atmosphere (Fig. 4). In general, these are too low to appear as prominences at the circumference. But by adjusting the spectroheliograph so as to photograph the disk with the red hydrogen line ( $H\alpha$ ), we can record the prominences themselves in projection. We can also render them visible in relief, by applying the principle of the stereoscope (q.v.), which unites into a single image two photographs taken from different points of view, and thus corresponding to the different images of a terrestrial object seen with the two eyes. In the case of the sun, the axial rotation provides the simplest means of obtaining the two images required. We combine for the stereoscope two photographs of the hydrogen *floculi* taken a few minutes apart, and thus obtain the stereogram here reproduced (Fig. 5). This is a negative, as the best effect is obtained in this way; i.e., all of the bright regions shown are actually dark, and vice versa. In examining Fig. 5 with a stereoscope, two roughly circular white spots will be seen to the right of the centre. These mark the positions of two sun spots, which were members of a group containing several other spots here concealed by the overlying atmosphere. The structure of the chromosphere is like that of a field of grain, and the tips of the slender columns, which appear like bright dots (in reality dark) in the undisturbed region near the edges of the picture, are drawn out by the wind that blows towards the spot group into filaments, which finally end abruptly. In the adjoining region, of honeycomb structure, beneath which the spots lie, a long ridgelike prominence rises precipitously to an elevation of several thousand miles. The appearance of relief is due *in part* to pseudo-stereoscopic effects.

Just above the centre of the picture there is a crater-like cavity resembling a chrysanthemum. This marks a whirling vortex immediately over a sun spot. When such vortices in the chromosphere were discovered with the spectroheliograph on Mount Wilson in 1908, it was inferred that the sun spots below them might also be vortices, similar to terrestrial tornadoes or waterspouts. Recent advances in physics had shown that all hot bodies give out electrically charged particles, and a whirling mass of such

# SUN

1. Direct Photograph of Sun, Aug. 7, 1908.  
The dark spots are sun-spots.

2. Chromosphere and prominences, photographed with spectroheliograph.

3. Solar prominence 80,000 miles high, photographed with spectroheliograph.

4. Spectroheliogram showing bright clouds of calcium vapor (Calcium flocculi.) Photographed with spectroheliograph.

5. Hydrogen flocculi surrounding sun-spots, showing right and left-handed vortices. Photographed with spectroheliograph.

## SUN

6. Steroscopic view of the solar atmosphere above a group of sun-spots, August 7, 1915.

7. Portion of sun-spot spectrum, showing effects of magnetic field.

particles would produce a magnetic field if the negative charges preponderated over the positive, or vice versa. Hence a magnetic field was sought for in sun spots.

Zeeman discovered in 1896 that the single lines in the spectrum of iron and other substances are split up into three or more components if the luminous vapor which produces them is observed between the poles of a powerful magnet. Moreover, the light of these components is polarized in a perfectly characteristic way, so that either component can be cut off at will by means of suitable polarizing apparatus. This test, applied on Mount Wilson in 1908 to the lines of iron and other substances in the spectra of sun spots, which had previously been found to consist of two or more components, showed the distinguishing features of the Zeeman effect. In Fig. 7, which is reproduced from a photograph of a sun-spot spectrum taken with the 75-foot spectrograph of the 150-foot tower telescope of the Mount Wilson Observatory, the iron line  $\lambda 6173$  is plainly resolved into three components, of which the two outer ones are cut off alternately on the successive horizontal strips (which correspond to the strips of a quarter-wave plate used with a Nicol prism over the slit of the spectrograph).

Hundreds of lines in the spot spectrum exactly correspond in number of components and polarization phenomena with their laboratory counterparts, leaving no doubt that sun spots are electric vortices, containing magnetic fields of intensities sometimes as great as 5000 gauss. As a single glance at a spot spectrum shows whether the red or violet component of a Zeeman triplet is transmitted by a known arrangement of the polarizing apparatus, the magnetic polarity, corresponding to the direction of whirl, of the spot vortex can be learned. In this way the association of spots of opposite polarity in pairs and the law of their rotation in the northern and southern hemispheres have been determined.

The inference that sun spots are vortices, here based upon the presence of overlying vortices in the chromosphere and the existence of magnetic fields in the spots themselves, has been confirmed by the discovery of Evershed, who proved that the spot vapors are whirling rapidly by measuring their velocities of approach and recession with the spectrograph. His results, confirmed and extended by St. John, show that the vortices in the chromosphere are secondary phenomena, induced by the low-lying spot vortices in the photosphere below them.

Following up the discovery of magnetic fields in sun spots, the Mount Wilson observers have proved by similar methods that the entire sun is also a magnet. Its polarity is the same as that of the earth, while the intensity of its magnetism is about 80 times as great. The sun's magnetic axis also does not coincide exactly with its axis of rotation, but the inclination is apparently considerably less than in the case of the earth.

Extending far out beyond the chromosphere and prominences, and usually recognized as the sun's outermost envelope, is the corona. It is visible only at the time of total eclipse, when the central part of the solar disk is completely obscured. The appearance of the corona at such times is very sudden; the advancing edge of the moon slowly and gradually covers more and more of the sun's surface, until finally only a sickle-

shaped filament remains. Then suddenly this too disappears, and on the instant the superb corona bursts into view, truly one of the most magnificent objects in the whole range of nature's phenomena. The inner corona, close to the solar disk, is relatively very bright; farther out it fades rapidly into a beautiful crown of filmy light. There are threadlike streamers, interlacing with complex involutions, and extending often many millions of miles into space above the solar surface.

Although observed visually from the most ancient times, it was not until the application of photography to astronomical observation that we have been able to fix with some approach to certainty the details of the coronal structure.

The corona undergoes more or less regular changes in form in a period of about 11 years, showing long equatorial extensions at the time of sun-spot minimum and a more uniform distribution in all directions at the spot maximum. Analysis of its light indicates distinct radial polarization in the outer corona, but this decreases and finally disappears near the sun. This polarization is doubtless caused, as in the earth's atmosphere, by diffuse reflection within the corona. Spectroscopically the corona reveals the presence of rare luminous gases, possibly containing in suspension particles of solid or liquid matter, but no existing theory will explain quite satisfactorily its mechanical construction. Possibly electric forces are wholly or partly responsible for its existence and radiation; certain it is that we still have in the corona one of the "pending problems" of astronomy. Very interesting questions are raised by a study of the sun's radiation of light and heat.

The extensive investigations of Abbot, made with an improved form of Langley's spectrobolometer and various types of pyrheliometers, have yielded a result of 1.93 calories for the so-called "solar constant" of radiation. This is the amount of radiation received from the sun in one minute on an area of one square centimetre at a point just above the earth's atmosphere. Although still retaining the old name of "solar constant," this quantity has been found by Abbot to undergo variations, which are often as great as 5 per cent within a single week. These short period variations appear to be irregular in character, both in amount and time. But there is also a small but distinct change of the solar radiation corresponding with the sun-spot period as Abbot's average values of the "solar constant" increase with the number of spots on the sun.

The temperature of the sun, as derived from determinations of the position of maximum intensity in its energy spectrum, is of the order of 6,000° C., or nearly twice that of the electric arc light. The source of its vast amount of light and heat has been for a long time a mystery. It cannot be a question of combustion, because in that case the sun would have been consumed long ago, even if made of solid coal. The theory most commonly accepted is due to Helmholtz. It assumes that the sun's bulk is slowly contracting, and that the energy thus produced is turned into heat. It has been computed that a diminution of 150 feet annually in the sun's radius would be sufficient to account for the heat developed. But as the past duration of the solar radiation as thus computed falls short of the demands of the geologists, it is possible that radioactive phenomena, involving the spontaneous disintegration of atoms,

may account for the additional heat required. See RADIOACTIVITY.

The rotation of the sun on its axis occupies about 25 days (at the equator). This period is determined by watching the spots, faculae, or flocculi, go around with the sun and also by spectrographic observations of the approach and recession of the eastern and western limbs. The rotation axis is inclined about  $7^\circ$  to the ecliptic plane, like that of the earth; if continued to the celestial sphere, it would pierce it midway between the bright star Vega and the polestar. And there is one very peculiar feature in the rotation due perhaps to the fact that the sun's vast bulk has not yet been completely transformed from the gaseous to the liquid or solid stage. The equatorial regions rotate faster than those in higher latitudes, showing the existence of strong rotary surface currents of different velocities. Moreover, Adams and others have shown that the absolute velocity and the law of its variation from equator to poles vary at different heights in the solar atmosphere. No thoroughly satisfactory explanation of these phenomena has yet been obtained by astronomers.

Olcott, *Sun Lore of all Ages* (New York, 1914); also Mount Wilson Solar Observatory, *Contributions* (Chicago, Washington, 1905 et seq.); *Astrophysical Journal* (ib., monthly). See ASTRONOMY; APEX OF THE SUN'S WAY; ECLIPSE; ORBIT; PERTURBATIONS; PLANETS; SOLAR SYSTEM.

**SUN, TEMPLE OF THE.** An immense temple in ancient Rome erected by Aurelian, after the taking of Palmyra (q.v.) on the site of the early Pulvinar Solis on the Quirinal Hill. Consult S. B. Platner, *The Topography and Monuments of Ancient Rome* (2d ed., Boston, 1911).

**SUN AND LION, ORDER OF THE.** A Persian civil and military order of merit with five classes, founded in 1808 by Shah Fath Ali on the model of the French Legion of Honor. The decoration is a silver star, bearing a lion with a sword. See Plate of ORDERS.

**SUN ANIMALCULE.** See HELIOZOA.

**SUN BEAR.** See BEAR, *Sun Bear*.

**SUNBIRD.** A bird of the tropical passerine family Nectarinidae, which may be regarded as occupying nearly the same place in the Old World as do the humming birds in America. They are all of small size, although none are so small as the smallest humming birds, which they rival in brilliancy of plumage. Like them, they feed partly on the nectar of flowers, which they suck by their long bill, but chiefly on the minute insects which the flowers attract; they do not, however, flutter on the wing when feeding, like humming birds, but perch on or beside the flower into which the bill is to be inserted. The species are very numerous, and are natives of the southern parts of Asia, the Eastern Archipelago, and Africa. The resplendent metallic plumage belongs only to the male, and only to the breeding season. They have been described

and depicted in a magnificently illustrated monograph by Shelley, *The Nectarinidae* (London, 1876-80). See Plate of CREEPERS.

**SUN BITTERN** (so called because of its brilliant ocellated plumage). A curious bird of South and Central America, about the size of a chicken, allied to the cranes and more closely to the kagu (q.v.), the two species of which constitute the genus *Eurypyga* and the family Eurypygidae. It haunts river banks, feeds upon small fish, crustaceans, and insects, and utters a soft or plaintive, long-drawn whistle. In the mating season it executes a fantastic dance, with its wings spread about its head, showing a pattern comparable to the sun's rays. Its nest is a rude affair in a bush or on a low tree branch. The best-known species is *Eurypyga helias*, which is beautifully variegated with brown, black, and white tints. This bird is often domesticated by the Brazilians. Consult Alfred Newton, *Dictionary of Birds* (New York, 1896). See Plate of BUSTARDS.

**SUNBURN, ERYTHEMA SOLARE.** The local effects of exposure to the sun's rays may be slight and confined to a little redness and tingling, or may produce severe blistering and loss of the superficial layers of the skin. Freckles (q.v.) are made more apparent by the sun's rays, particularly in persons of fair complexion, but it is doubtful if they are actually caused by the sun. Sunburn may be prevented to some extent by protecting the exposed parts of the body by sunshades, veils, etc., by grease paint, cold cream, and face powder. Slight cases of sunburn require no treatment, or may demand only the application of bismuth, boracic acid, or zinc oxide, or sprinkling with rose water. Severe cases, with blistering and much pain, are treated in the same manner as burns elsewhere on the body. See BURNS AND SCALDS.

**SUNBURY.** A borough and the county seat of Northumberland Co., Pa., 54 miles north of Harrisburg, on the Susquehanna River and on the Pennsylvania and the Philadelphia and Reading railroads (Map: Pennsylvania, H 5). There are the Mary M. Packer Hospital, the courthouse, jail, and two parish houses. Sunbury has a silk mill and converting works, two coffin works, planing mills, a foundry, machine shops, flour mills, and large repair and machine shops of the Pennsylvania Railroad. Sunbury was founded in 1772 on the site of an old Indian village and of Fort Augusta, built in 1756, during the French and Indian War. It was first incorporated in 1797. Pop., 1900, 9810; 1910, 13,770; 1915 (U. S. est.), 15,859; 1920, 15,721.

**SUNDA** (sūn'dū) ISLANDS. A name commonly applied to all the islands of the Malay Archipelago lying west of the Molucca and Banda seas, and separating the China Sea from the Indian Ocean (Map: East India Islands, B 6). They include the four large Sundas, Sumatra, Java, Borneo, and Celebes, with their dependent islands, and the lesser Sundas, Bali, Lombok, Sumbawa, Flores, Sandalwood Island, Timor, and others extending in a chain eastward from Java. The Sunda Islands are named from the Sundanese, ethnographically a Malayan people of the western part of Java. They are shorter in stature than the Javanese proper, and somewhat more brachycephalic. They have also been less influenced by Hindu culture.

**SUN DANCE.** The great annual religious ceremony common to all the tribes of the Plains with the exception of the Comanche and perhaps

one or two others. Its purpose varied, but in general it was performed to promote the prosperity of the tribe. Although anticipated as a yearly tribal event in some tribes, it is usually made or organized on each occasion in fulfillment of a vow by some particular individual in gratitude for recovery from sickness or for some other blessing. The Crow held the ceremony exclusively to avenge the death of a relative. The management of details is in charge of certain priests, together with the warrior societies. The dance usually takes place about the beginning of summer and with all its attendant ceremonies lasts more than a week, the dance proper continuing four days and nights. The entire tribe assemble for the occasion and pitch their tepees in a great circle, in the centre of which is erected the medicine lodge of leafy cottonwood saplings. The centre pole of the lodge is decorated with streamers and symbolic paints, besides which a sacred bundle, usually wrapped in a buffalo skin, is fastened near the top. The centre pole is cut down by the women with much ceremony. The dancers are stripped and painted, the paint design differing in symbolic character at each stage of the dance, and are prohibited from eating or drinking during the four days of the dance. Among most of the tribes they formerly also subjected themselves to voluntary torture by leaning their weight upon ropes fastened to wooden skewers driven through the flesh of their breasts and shoulders. In the Mandan Okipa, an analogous ceremony, this torture was carried to an almost incredible degree; the victim was lifted completely from the ground and permitted to swing from the roof pole in this condition, after which one or more fingers were chopped off as a further sacrifice. Among the Kiowa such torture was unknown.

The dancers form a half circle about the centre pole, each one looking steadfastly upon the sacred bundle at the top and constantly facing the sun in its course, with their arms swinging at their sides, and holding between their teeth whistles of eagle bone with which they keep up a continual shrill whistling. At the west end of the medicine lodge is an altar of bushes and variously decorated twigs within which are the sacred buffalo skull, the sacred pipe, and other ceremonial objects. On another side are the drummers, who sing the songs of the sun dance to the accompaniment of a powerful drum. Throughout the ceremony there is a rapid succession of ceremonial performances, including addresses, feasting, giving of presents, and initiation of new members into the various societies. Owing to the torture features, the dance has been almost completely suppressed by the government. Consult: G. A. Dorsey, "Arapaho Sun Dance," "Cheyenne Sun Dance," and "Ponca Sun Dance," in *Field Museum of Natural History, Publications: Anthropological Series*, Nos. 75, 99, 102, 103 (Chicago, 1903-05); H. L. Scott, "Notes on the Kado, or Sun Dance of the Kiowa," in *American Anthropologist* (Lancaster, Pa., 1911); George Catlin, *North American Indians* (new ed., 2 vols., Philadelphia, 1913); R. H. Lowie, *The Sun Dance of the Crow Indians* (New York, 1915).

**SUNDARBANS**, *sun'dar-bünz'*, or **SUN-DEBUNDS**, *sün'der-bündz'*. The group of low islands forming the delta of the Ganges, British India (Map: India, F 5). Area, 7500 square miles. Only the northern part is inhabited, the southern being mainly jungle, some-

times submerged during floods, infested by tigers, leopards, buffaloes, crocodiles, and snakes. The only town worthy of mention is Port Canning, connected with Calcutta by rail.

**SUNDAY** (AS. *sunndæg*, OHG. *sununtag*, Ger. *Sonntag*, Sunday, from AS. *sunnan*, sun + AS. *dæg*, Ger. *Tag*, day). The first day of the week, observed by Christians almost universally as a holy day in honor of the resurrection of Christ. For some time after the foundation of the Christian Church the converts from Judaism still observed the Jewish Sabbath to a greater or less extent, at first, it would seem, concurrently with the celebration of the first day; but before the end of the apostolic period, Sunday, known as the Lord's day, had thoroughly established itself as the special day to be sanctified by rest from secular labor and by public worship. The hallowing of Sunday appears uncontestedly as a definite law of the Church by the beginning of the fourth century; and the Emperor Constantine confirmed the custom by a law of the state. Throughout the mediæval period the authority of the Church was so universally recognized that secular legislation in this regard was almost unnecessary. The Catholic church then required, and still requires, abstinence from servile work on that day, and the assistance at mass of all who are not lawfully hindered.

In the mediæval period the courts were presided over or dominated by the clergy, and Sunday early became in the legal sense a *dies non* (q.v.), on which legal proceedings could not be conducted. By the common law, however, all other business might lawfully be transacted on Sunday. The first substantial limitation of this right was imposed by the Statute 5 and 6 Edw. V, c. 3, which provided that all secular labor should be unlawful on Sunday, except in cases of necessity. This was supplemented by the sweeping Act of 29 Car. II, c. 7, which prohibited all worldly business on the Lord's day, except where absolutely necessary or for charity. These statutes have been substantially followed in practically all of the United States. The New England States were the first to regulate the observance of Sunday by a series of statutes. The Constitution of the United States prohibits the restriction of religious liberty or the enforcement of religious observances, and therefore, in law, Sunday is regarded merely as a civil day, which is a convenient one for the suspension of business, because of its observance as a holy day by a great majority of the people. These statutes are constitutional as a valid exercise of the police power. Works of necessity and great public convenience are usually excepted. Thus, a physician may carry on his practice, making lawful charges for his services; drug stores may keep open; transportation lines may handle freight and passenger traffic; milk dealers are usually permitted to deliver their product; and all persons whose business conduces to the public health are permitted to continue their activities. Where a cessation of operations would cause great financial loss an exception is commonly made.

Where a person is traveling on Sunday in violation of law, and is injured, he is not precluded from recovering damages if he is otherwise entitled thereto. Although contracts entered into on Sunday were valid at common law, the courts of many States have interpreted their Sunday statutes as including this kind of a business transaction. A payment of a debt on

Sunday is generally held to discharge the obligation. Wills executed on Sunday may be probated in most jurisdictions. It is an almost universal rule, however, that legal process may not be validly served on Sunday. In most States the legal Sunday begins at midnight on Saturday night and continues 24 hours. In a few New England States Sunday ends at sunset. Many States exempt Hebrews and others who observe Saturday or some day other than Sunday as a holy day from the operation of the Sunday laws, but if such persons do not keep sacred any other day, they must suspend business on Sunday.

The need of one day in seven for rest from labor has long been recognized from an economic standpoint also, more and better work being produced by the rest. Sunday labor in the United States is, however, increasing. That the increase is general is shown by the growing opposition of the labor unions, and their frequent demands for shorter hours throughout the week, on the ground that they have no assurance of the Sunday respite.

**SUNDAY, WILLIAM ASHLEY**, popularly known as **BILLY SUNDAY** (1863- ). An American evangelist, born at Ames, Iowa. Between 1883 and 1890 he was a professional baseball player with the Chicago, Pittsburgh, and Philadelphia teams of the National League and in 1891-95 served as assistant secretary of the Y. M. C. A. in Chicago. He began his evangelistic work in 1896, and in 1903 was ordained a Presbyterian minister. The number of his converts for the period 1904-13 was estimated at 75,000. Perhaps his most successful revival was the one conducted by him at Philadelphia in 1915. By some Sunday was considered a sensationalist, and by others a sincere man possessed of great power to move his hearers. His extreme unconventionality of method brought him most criticism. Consult W. T. Ellis, "*Billy Sunday, the Man and his Message*" (Chicago, 1914).

**SUNDAY LETTER.** See **DOMINICAL LETTER**.

**SUNDAY SCHOOLS.** An agency of the Church for instructing learners of all ages. It seems that when the Jews lost their national life they sought to retrieve their greatness through education. Hence about 70 B.C. they established schools in connection with their synagogues. Probably these suggested to the early Christians the idea of catechetical instruction—an idea that was carried into Egypt and through Mesopotamia to Armenia, where, in the fourth century, Gregory the Illuminator propagated the faith by compelling the attendance of children in Bible schools. During the Middle Ages Waldenses, Albigenses, and Lollards carried on this Bible-study tradition. During the seventeenth and eighteenth centuries, however, direct Bible teaching was set aside for the memorization of answers in the catechism.

In England the rebirth of the Sunday school in 1780 was due to Robert Raikes (q.v.). Aided by John Nichols, editor of the *Gentleman's Magazine*, George Whitefield, John and Charles Wesley, and even by the Queen, Raikes was able to expand his work. A Sunday-school society was established in 1785 which during the next 10 years distributed 9200 spelling books, 25,000 Testaments, and 5300 Bibles to 1012 schools and 65,000 pupils. By the close of the century the employment of teachers had ceased, and in 1811 volunteer instructors were caring for 400,000 children, despite a threatened stoppage of the

work by the Archbishop of Canterbury, who feared the influence of secular instruction on Sunday.

In America Sunday schools were established at Plymouth in 1669, at Roxbury in 1674, and at other Puritan settlements where, after the morning service, the children were taught in the Scriptures and catechism by men and women. Ludwig Thacker conducted a school in the Dunker community near Philadelphia from 1744 until 1777, when the battle of Brandywine made it necessary to use the community buildings as hospitals. After the Revolution the Sunday-school idea was advanced by the Methodists, for John Wesley in his "Discipline" had urged on each church the importance of teaching its children whenever 10 could be gathered together. Bishop Asbury established a Raikes school. In 1793 a negress, Kate Ferguson, who had never heard of Raikes, organized a poor children's school in New York City. Other denominations began to interest themselves in the problem of instruction, and the result was the organization of the First Day or Sunday School Society of Philadelphia, Jan. 11, 1791. Of this, Bishop White of the Protestant Episcopal church was president and Matthew Carey, a Catholic, secretary. The organization was followed by that of the Female Society for the Promotion of Sabbath Schools, whose leaders were benevolent women of several denominations. In February of 1816 the men of New York similarly organized, and the Boston Society for the Moral and Religious Instruction of the Poor came into being. The next year the Philadelphia Sunday and Adult School Union, embracing members outside of the city as well as those within, employed a missionary and issued Scripture tickets and other matter. The missionary organized 60 schools.

**American Sunday School Union.** These various movements led naturally to the formation of the American Sunday School Union in Philadelphia, May 25, 1824. Immediately this society began to send its missionaries into the Western wilderness. Perhaps the most effective was Stephen Paxson, who, traveling from the Alleghanies to the Rockies and from the Great Lakes to the Gulf, organized 1314 schools with 83,405 pupils before he retired in 1868. As a general thing this society has not worked in the large cities, preferring to send its missionaries as pastors to people remote from the organized churches. It has always been strictly undenominational, leaving its schools to develop into the kind of churches that appeal most to them. It carries on its work over the whole United States, which it divides into 10 districts, each under a superintendent to direct the missionaries. Its report for 1915 shows that the Union organized during that year 1368 schools with 47,000 pupils, visited 188,652 families, and distributed 34,443 Bibles, Testaments, and hymn books, and books to the value of \$21,482.95. (Of its schools previously organized 86 became churches during this year.)

**International Sunday School Association.** Between 1820 and 1830 local conventions were held, the fruits of which suggested a large representative meeting. So in 1832 delegates from 15 States came together at Philadelphia as the First National Convention. A similar body met several times before 1872; but that year marks the adoption of a uniform system of lessons. In 1875 the movement became international, and since 1889 it has been world wide. From the report of the last convention held in Chicago in

1914 it is gathered that North America has 175,685 Sunday schools with 18,441,036 pupils and 1,690,000 teachers, or double the numbers reported at the Chicago convention of 1887. These schools send delegates to 2592 county conventions out of a possible 3442, and to other general meetings; so that, in 1914, 58,435 gatherings were held. In all of these conventions the departmental work and other phases of the International Convention are emphasized. Three divisions of pupils are recognized: elementary, secondary, and adult; four departments organized: teacher training, missionary, visitation, and temperance; and a general emphasis laid on evangelistic effort and workers' conferences. The most striking advance in the last triennium of the association's history was the increased interest in adult Bible study. In all, 50,000 adult classes are organized with 2,000,000 members. Another great advance has been made in the so-called "teen age" group, one effect of which was the admission into the various churches of 1,055,444 pupils during 1915.

**Denominational Work.** The various denominations have been greatly benefited by their joint effort to establish the Sunday school on a solid pedagogical basis, for they have received members trained to do their work. Most of the churches have encouraged the growth of Sunday schools within their own ranks by establishing boards and publishing houses to furnish the various lesson helps, references, and books, children's papers, cards, and material that the new teaching requires, at as near cost as possible. They send out missionaries to organize schools. But they are as constantly receiving churches born of both the American Sunday School Union and the International Sunday School Association as they are giving their talent, their money, and their united efforts to these organizations—the one undenominational, the other interdenominational.

**Lessons and Helps.** The first movement towards standardizing the courses of study was made by the Reverend, afterward Bishop, John H. Vincent, who in 1865 published the *Teacher*, a periodical containing 24 lessons for the year, with "Parallel Passages, Persons, Places, Dates, Doctrines, and Duties." Rev. Edward Eggleston, author of *The Hoosier Schoolmaster*, continued the publication after 1869 and issued 35,000 copies annually. The success of the *Teacher* brought the question of uniform lessons before the National Convention in 1872. The result was the appointment of a lesson committee which, including English and French correspondents, has since compiled what are known as the *International Lessons*. They were designed to complete the study of the Bible in six years, the average Sunday-school life of the child. A special feature has been the Temperance Lesson, included in each quarter's assignment. The American Sunday School Union was a pioneer in publishing these lessons and other matter, including books for both pupils and teachers forming the first circulating library for Sunday schools.

**Grading.** Another important movement led to the grading of the schools. In 1891 the Rev. Erasmus Blakesley, who had designed a graded course of study, helped to organize the Bible Study Union. From this came a system of lessons beginning with a simple sewing card for infants and ending with an intensive Bible study for adults. The International Lesson

Committee, in 1895, recognized the demand for special primary lessons by issuing an optional course for beginners with its regular uniform lessons; but it was not until 1909 that the committee published its graded course, now offered as a choice with the uniform lessons.

**Educational Efficiency.** The recognition of value in the graded lessons has helped to solve other educational problems. Early in the twentieth century thousands of schools began to apply the principles of secular education. Children of the same grade in the public schools have been grouped in the corresponding Sunday-school grade; and to their biblical study have added the aids of the public school from the kindergarten to the college (sand-boxes, manual art, maps, notebooks, references, applied Christianity) so that, not only have students received definite ideas of the lives and times of biblical personages, but they have also connected biblical matter with current affairs in a very real way. This ideal of education has demanded normal training. In 1854 the Unitarians began to prepare their teachers in institutes. In 1864 John H. Vincent was a leader in a similar movement among the Methodists. In 1874 the Chautauqua began its work of training Sunday-school teachers that later broadened into several secular studies. Since 1880 normal instruction for Sunday-school work has been generally recognized. This instruction is given in departments of the schools, in institutes connected with the conventions and in courses conducted throughout the year. In 86 cities specialists are organized into faculties under deans to give lectures to teachers as do college faculties.

**Organized Classes.** Another idea that has proved popular and effective is that of the organized class. Such a class, whether of the teen age or adult department, with its own government, ways and means to stimulate interest and evoke suggestions for service to the church and community, has so proved its effectiveness that there are now 100,000 organized classes in America. The names Baraca (blessing) and Philothea (lovers of truth), given to a young men's and a young women's class respectively in the early nineties, have come to mean the most in this organized class movement, both because there are 9000 classes with a total membership of 1,000,000 in 32 denominations, enlisted under these names, and because through business method, social effort, Bible study, lectures, addresses, and prayer circles, all inspired by a carefully prepared propaganda, these classes have appealed and are appealing to groups of people who apparently have little in common.

**Federation.** Over 250 men are now employed to give all of their time to federating the activities of the Sunday school. They call conventions, establish institutes, open reading rooms and museums, in short, inspire all phases of the work as outlined by the International Sunday School Association. In this way the Sunday school is advancing educationally, socially, and religiously as well as numerically.

**Roman Catholic Sunday Schools.** The number and functions of the Roman Catholic Sunday schools in the United States depend to a certain extent upon the condition of the parochial schools, where the teaching of religion has the first place. Wherever there are parochial schools, the Sunday school is of secondary importance; but the need of religious instruction in the parishes which have no parochial schools was

met in 1905 by an encyclical of Pius X, who decreed that all Catholic pastors, and generally all those who had the care of souls, should give religious instruction to boys and girls on Sundays, feast days, and other stated times of the year. Historically considered, Catholic Sunday schools are the descendants of the early Christian catechumenal and catechetical classes and schools and their successors in the Middle Ages. The Council of Trent (q.v.) confirmed and improved upon the previous decrees of Church councils in regard to the religious instruction of the young, and St. Charles Borromeo (q.v.), who is often called the pioneer of the modern Sunday school, founded in the archdiocese of Milan organizations for the religious education of boys and girls. In 1912 there were 5119 parochial schools in the United States, and in 1914 there were about 9000 churches without them, so that the decree of Pius X has made Sunday schools an official and practically universal means of religious instruction in the church in the United States. In 1915 there were between 1,500,000 and 1,600,000 children in attendance. The parish priest is superintendent by virtue of his office and has entire authority, subject to his ecclesiastical superiors, but he may appoint a representative. He is assisted by professional religious teachers, members of religious orders, and by laymen and women. Grading is based in general upon the requirements of preparation respectively for first confession, first communion, and for the instruction of those who have received their first communion. The ecclesiastical authorities have adopted to a certain extent the grading established in secular schools. They have also authorized textbooks for the assistance of teachers and a series of catechisms arranged according to the ages and capacities of the pupils.

In Canada each Catholic parish has a Sunday school, and in general it is subject to the same rules respecting authority, grading, and instruction as those which obtain in the United States. Owing to the protection which the educational rights of minorities in the Canadian provinces enjoy (see CANADA, *History*), parochial schools are well supported, and the Catholic Sunday school is relatively less important than in the United States. There are no authorized Sunday-school statistics.

In Great Britain Catholic Sunday schools are ordinarily established in connection with Catholic day schools. In many cases, however, where organization and facilities are lacking, the children are given catechetical instruction in churches, where graded questions are asked and explanations given. The Sunday schools have no definite official sanction, but are well attended.

**SUNDERBUNDS.** See SUNDARBANS.

**SUNDERLAND.** A seaport in the county of Durham, England, 14 miles northeast of Durham, at the mouth of the Wear (Map: England, E 2). It is one of the great coal-shipping ports of the world. Shipbuilding is an important industry. Machinery, glass, earthenware, chemicals, paper, ropes and chains, anchors, and other iron wares are extensively manufactured, and fishing is carried on to a considerable extent. In the vicinity are rich coal mines, of which the Pemberton, 2286 feet deep, is said to be the deepest in existence. On both sides of the river are extensive wet and dry docks, much of the area of which has been reclaimed from the sea. The harbor, defended by batteries, is formed by two great piers, one 650 yards and the other 590 yards in length. Sunderland is a well-built town with broad streets. There are a fine town hall, an assembly hall, handsome club houses, a large infirmary, and a spacious workmen's hall. The public park contains 70 acres. The borough was extended in 1867 and again in 1895; it includes the townships of Bishopwearmouth, Monkwearmouth, and Monkwearmouth Shore. The Monkwearmouth section dates from a monastery of the seventh century, in which the Venerable Bede spent most of his life. Pop., 1901, 146,565; 1911, 151,132.

**SUNDERLAND, CHARLES SPENCER**, third EARL OF (1674-1722). An English political leader. He was the second son of the second Earl of Sunderland, and became Lord Spencer on the death of his elder brother in 1688. In 1700 he married Lady Anne Churchill, second daughter of the Earl of Marlborough. In 1702, on the death of his father, Spencer succeeded to the title. Through the influence of Marlborough,

Sunderland obtained several important posts, and became a member of the famous Whig Junta, which for a time controlled the whole government. In 1720 Sunderland brought about the establishment of the notorious South Sea Company (q.v.). When the crash came it was found that Sunderland had received a bribe of £50,000 from the company, and though he was acquitted by a party vote, he had to resign his offices. He retained, however, considerable influence until his death. Sunderland seems to have been a disagreeable and treacherous politician. He was a collector of rare books, and a patron of Addison and other men of letters.

**SUNDERLAND, JABEZ THOMAS** (1842-). An American Unitarian minister, born at Howarth, Yorkshire, England. He was educated at Madison (now Colgate) University, at the University of Chicago, and at the Union Baptist Theological Seminary of Chicago. Later he became a Unitarian, and was pastor of churches in the United States, Canada, and England. On commission from the British Unitarian Association he visited India in 1895-96, lecturing subsequently on religious conditions in that country. As Billings lecturer of the American Unitarian Association he visited countries of the Far East in 1913. From 1886 to 1895 he edited the *Unitarian Monthly*, and he wrote: *A Rational Faith* (1878); *What is the Bible* (1878); *The Liberal Christian Ministry* (1889); *The Bible: Its Origin, Growth, and Character, and Place among the Sacred Books of the World* (1893); *Liberal Religion in India* (1896); *James Martineau* (1905); *Oh, to be Rich and Young* (1910).

**SUNDERLAND, ROBERT SPENCER**, second EARL OF (1640-1702). An English politician. He was the only son of Henry Spencer, who was raised to the peerage in 1643. He was educated at Christ Church, Oxford, served as Ambassador at Madrid, at Paris, and at Cologne, and in 1679 was made a Secretary of State for the Northern Department and a member of the smaller inner cabinet with which King Charles II habitually conferred. Sunderland at first supported the Duke of York and then labored for the Exclusion Bill, which was to exclude the Duke from the succession. Thereby he lost the favor of Charles and his position in the Privy Council (1680). In 1682 he was restored to royal favor through the influence of the Duchess of Portland, mistress of Charles II, and the French Ambassador Barillon, and unscrupulously advocated the disgraceful French connection. He remained in office until the accession of James II, when his influence in the ministry became greater than ever. Although there is reason to believe he gave some encouragement to Monmouth in his rebellion, he managed to obtain the entire confidence of James, and in 1685 became Lord President and principal Secretary of State. In 1687 he privately conformed to the Roman Catholic church, and later professed this. Yet we find him in correspondence with the Prince of Orange, afterward William III. With masterly dexterity he contrived to deceive both his master and Barillon, keeping them in ignorance of events in Holland. When the Prince arrived in England, Sunderland and his wife went to Amsterdam, whence he wrote to the new monarch, claiming his favor and protection on the ground that he had all along been in his interest. In 1691 he was allowed to return to England, and in 1697 was made Lord Chamberlain.

Popular indignation, however, soon compelled him to resign. He spent the rest of his days at Althorpe, where he died Sept. 28, 1702. Consult T. B. Macaulay, *History of England* (Boston, 1901).

**SUN'DEW'** (so called from the dewlike drops exuded, especially in the sunlight), *Drosera*. A beautiful and interesting genus of about 75 species of plants of the family Droseraceæ, several species of which are natives of American bogs, etc. A common species is the round-leaved sundew (*Drosera rotundifolia*). Its leaves all spring from the root, and spread out in a rosette, from the centre of which springs the flower stem or scape with a raceme of flowers all on one side. The leaves of this and the other species are fringed and beset in all parts with hairs, which bear at their extremity viscid

SUNDEW (*Drosera rotundifolia*).

glands, which fold up when irritated, imprisoning insects and digesting them through the action of enzymes secreted by the plant. Consult Charles Darwin, *Insectivorous Plants* (new ed., New York, 1900). See cut in article CARNIVOROUS PLANTS.

**SUNDIAL**. See DIAL AND DIALING.

**SUN DOGS**. See HALO.

**SUNDSVALL**, suns'vål. A seaport in the Län of Västernorrland, Sweden, 28 miles south by west of Härnösand, on the Gulf of Bothnia (Map: Sweden, F 5). It is known for its extensive lumber interests, and is engaged in ship-building and the manufacture of wood pulp, iron, and steel. Pop., 1901, 15,087; 1910, 16,854.

**SUNERKOR**. See HAMADRYAD.

**SUN FEVER**. See HEAT STROKE.

**SUN'FISH'**. The name of a variety of fishes; also given by sailors to jellyfish. 1. In the United States a group of numerous and familiar fishes of streams and ponds, related to the bass, and forming several genera of the family Cen-

trarchidæ (q.v.). All are of small size, 6 to 10 inches long, oval in shape, and much compressed. All are excellent eating. They are brightly colored, especially in the breeding season, and may be known by the black flap to the posterior edge of the gill cover. Their feeding and breeding habits are similar to those of the freshwater bass (q.v.). See Plate of DARTERS and SUNFISH; and consult Jordan and Everman, *American Food and Game Fishes* (New York, 1914).

2. One of the strange oceanic fishes of the family Molidae, related to the Diodontidæ; especially *Mola mola*, which seems to be composed of a huge head with small fins attached. (See Plate of ROCKFISH, SUNFISH, ETC.) They reach a weight of 300 to 1500 pounds, are scaleless, dull in color, clumsy, and often lie inert like a huge gray blanket on the surface of the sea sunning themselves and bending with the movements of the waves. The young are more fish-like, and were long considered entirely separate. They are of no use as food. There are about six species, one of which (*Ranzania truncata*) is called "king of the mackerels." Consult Bashford Dean, *Fishes, Living and Fossil* (New York, 1895).

3. The threadfish (q.v.) (*Alectis ciliaris*).

**SUNFLOWER** (probably so called from its yellow radiate disk), *Helianthus*. A genus of large herbs of the family Compositæ, containing numerous, mostly perennial, species, all natives of America. The common sunflower (*Helianthus annuus*), an annual, one of the most important species in cultivation, sometimes attains a height of 20 feet and produces flower heads from 1 to 2 feet in diameter. In temperate climates it ordinarily grows from 5 to 8 feet high. This species has become widely distributed throughout the United States as a weed. Another annual species, *Helianthus petiolaris*, is common in the west and the southwest. The sunflower was introduced into Europe about the middle of the sixteenth century. In Egypt, India, and southern Europe, especially in Russia, the plant is extensively grown for its seeds, which are eaten like nuts, and for their oil, which is used for culinary purposes. The oil is also used in the manufacture of varnishes on account of its drying properties, which, however, are inferior to those of linseed oil. It is also used in soap making and other manufactures. Sunflowers are cultivated somewhat in the United States and Canada for ornament, for forage, and for seed. On light, well-drained, well-tilled, and fertile soil a yield of from 30 to 50 bushels of seed per acre may be obtained. The preparation of the soil and its subsequent cultivation is similar to that for corn, but the distance between plants in the row should be from 12 to 16 inches. From 10 to 15 pounds of seed is required per acre. The heads are harvested shortly before they are thoroughly ripe to prevent loss of seed. Before storing they are carefully dried to prevent molding. The seeds are threshed out with flails. The average composition of the plant is water, 85.2 per cent; protein, 1.7; fat, 1.0; nitrogen-free extract, 6.2; crude fibre, 4.0; ash, 1.9. Of the seeds, water, 8.6 per cent; protein, 16.3; fat, 21.2; nitrogen-free extract, 21.4; crude fibre, 29.9; ash, 2.6. Of sunflower seed cake, water, 10.8; protein, 32.8; fat, 9.1; nitrogen-free extract, 27.1; crude fibre, 13.5; ash, 6.7.

The whole plant and the seeds have been used to a limited extent as a feeding stuff, especially

when mixed with horse beans and corn fodder for making silage. The seed is frequently fed to poultry. The oil cake is fed especially in northern Europe to fatten animals.

There are a dozen or more species which are common in the United States, especially in the Ohio, Mississippi, and Missouri valleys, where they often become conspicuous by their abundance. The sunflower is the state flower of Kansas. *Helianthus tuberosus* is the Jerusalem artichoke.

**SUNG**, sŭng. One of the seven great Chinese dynasties. It was founded in 960 by Chao Kw'ang-yin, a descendant of a family of officials of the Tang dynasty (618-907), who had risen to high military command. With the Empire rent with disorder, and the hordes of the Liao Tatars threatening on the north, the army concluded to raise their general, Chao, to the throne. He at once proceeded to repel the Liao and unify the Empire by reducing the petty states. He introduced many reforms, and for 16 years ruled with great wisdom and ability. The Liao, however, continued to encroach on Chinese territory, and in 1126, during the reign of the ninth Emperor, established their authority over all of North China, styling their dynasty the *Kin* or "Golden." The Sung fled south to Hangchow (q.v.), which continued to be the capital of the diminished Empire of the southern Sung. Nine emperors ruled here until 1279, when Kublai Khan and his Mongols overthrew both the Kin and the Sung, and established the Yuen dynasty in 1280. Notwithstanding the harassments and encroachments of invading armies, the Sung period was one of great prosperity and advance in civilization and culture.

**SUNGA**, sŭn'gá. See HUMPED CATTLE.

**SUNGA'RIA**, or **DZUNGARIA**. A name vaguely applied to a region of undefined extent in Central Asia. It belongs to China, and the name is generally restricted to the region lying north of the Tarim Basin in East Turkestan, between the Tian-Shan and Altai Mountains, and west of Mongolia (Map: China, E 2). It is chiefly of historical significance, deriving its name from the Sungarians, who attained their greatest power about the middle of the seventeenth century, when their kingdom embraced the territory between the Kuen-lun and the Altai Mountains, extending westward to Lake Balkhash. About 1670 the ruler of Sungaria entered into conflict with the Chinese, who completely overran the country. The Chinese were driven out in 1710 and for a short time the rulers of Sungaria were masters of Tibet. In 1759 the Chinese, after long campaigns, destroyed the reestablished Sungarian Kingdom and made the country a part of their Empire, peopling it largely with colonists from China.

**SUNG-KO-LIN-SIN**. See SENG-KO-LIN-SIN.  
**SUN'NIUM**, DEMETRIUS OF. See DEMETRIUS OF SUNIUM.

**SUNIUM PROM'ONTO'RIUM**. See CAPE COLONNA.

**SUNKEN BELL**, THE (Ger. *Die versunkene Glocke*). A poetic play in blank verse by Gerhart Hauptmann (1896). It is a fairy drama, the chief human character of which is Heinrich, a master bell founder.

**SUNLIGHT CURE**. See HELIOTHERAPY.

**SUNN**. A plant (*Orotalaria juncea*) grown in India and some other warm climates for its fibre. See HEMP, SUNN; CROTALARIA, and illustrations on Plate of CRANBERRY, ETC.

**SUN'NA** (Ar. *sunnah*, custom, legal usage, tradition, from *sanna*, to establish a usage or law). In the original meaning among Moslems, the sayings and the example of Mohammed and his community, provided they are in accordance with the Koran, the meaning of which, however, is itself explained by the Sunna. As embracing traditional law, Sunna is divided into three parts: (1) what Mohammed did; (2) what he enjoined; and (3) what was done in his presence and not forbidden by him. The term is therefore (though incorrectly) used for the collections of moral and legal traditions known as *Hadith* (q.v.) traced to the prophet, which supplement the Koran, somewhat like the Mishna (q.v.), which supplements the laws of the Pentateuch. The Sunna not only comprises religious doctrines and practice, but also civil and criminal laws, and the usages of common life, the way to eat and to drink, to dress, and the like. For the credibility and canonicity of a tradition, it was originally necessary that it should have been *heard* by one truthful witness; but this law was much relaxed in later times. By the beginning of the ninth century a large number of individual collections known as *Musnads* had been produced by different theologians, but the first who sifted them critically, and without regard to any special theological system, was Buchari (810-887). His collection contains 7275 single traditions, 4000 of which, however, occur twice in the work. Muslim, a younger contemporary (817-873), supplemented Buchari with another collection, containing 12,000 traditions, again including 4000 repetitions. Besides these, there are canonical collections by Abu Daud (817-888), by Tirmidhi (830-914), a pupil of Buchari, and by Abu Maja (824-886), besides others that also enjoyed some measure of authority. The Sunna, as we have it in these collections, contains, broadly speaking, more truth than it is generally supposed to contain, and, critically used, is, besides the Koran, the most authentic source of a knowledge of Islam. A selection from the different collections (both canonical and otherwise), called *Mishkat Al Masabih*, has been translated into English by Matthews (Calcutta, 1809). The Arabic text of Buchari has been published by Krehl, *Le recueil des traditions musulmanes* (Leyden, 1862-68), and fragments of this work in German translation were embodied by Hammer-Purgstall in his *Fundgruben des Orients* (Vienna, 1810-19). Consult Ignaz Goldziher, *Mohammedanische Studien*, vol. ii (Halle, 1890).

**SUNNITES**, sūn'its (from Ar. *sunnah*, custom, legal usage, tradition, from *sanna*, to establish a usage or law). The orthodox sect in Islam. The term arose in distinction to several tendencies which early asserted themselves, but especially differentiates that section which denies the claim of the Shiites (q.v.) for the peculiar authority of Ali, as the sole legitimate successor of Mohammed. (See MOHAMMEDAN SECTS.) These Shiites fast developed their peculiar theological and constitutional theories, and so drove their opponents to an understanding of their own position; as they were content with tradition and with things as they were, they called themselves Sunnites, or Traditionalists. The differences rapidly developed into those of a political and ethnic character, the Shiites being found in the lands which were opposed to the Umayyads (see OMMIADS), as

Arabia, where independence was characteristic, and in Persia, which only by force of arms had submitted to Islam. But the decision between the two parties was by no means immediately reached. The fall of the Umayyads was brought about by Persian Shiite influences (750), although the new Abbasid dynasty which was installed soon threw in its lot with the Sunnites. In general the geographic centre of the Arab power, Mesopotamia and Syria, remained in the control of this party. But the Shiites maintained the contest. The latter as liberals and theosophists possessed a strong following, especially among the cultured, and they often enjoyed immunity under free-thinking caliphs. The Empire was honeycombed with Shiite secret societies like the Assassins (q.v.), and Shiite dynasties arose in Egypt and at Bagdad. (See SHIITES.) But by 1100 Sunnism was master in southwestern Asia. This party was able to maintain itself during the Mongol invasions, and with the favor of the Ottoman Turks it remains as the predominant body in Islam. At the present time orthodoxy outnumbers all its opponents by 10 to one, and commands not only the whole Turkish Empire, but the millions of Moslems in Africa, India, China, Malaysia, and the Philippines.

Within this conservative and orthodox body, apart from outer foes, there early developed all kinds of theological strife. Rationalistic and liberal parties developed, which opposed, one after another, the original principles of Islam, such as its views of God, and of heaven and hell, its doctrines of predestination and of the literal authority of the Koran. On the other hand, the crass views of the fanatical mob opposed anything like philosophy, even though orthodox. Traditionalism was not fitted to meet the dialectic methods of its opponents, who had learned from the ancient schools of culture, and was ignorant of the use of philosophy in self-defense. But the champion of orthodoxy arose in Ashari (born 882). A member originally of the Muta-zilite sect, which had gone to the extreme of rationalizing upon the faith and the Koran (see MOHAMMEDAN SECTS), he was led to the consciousness of this inconsistency, and openly abjured that heresy, henceforth devoting himself to the formulation of a scholastic philosophy in support of orthodoxy. This school encountered for long the opposition of the liberals and the ignorant, but about 1050 Ashari's triumph became evident. His philosophy was continued and popularized by Ghazali (q.v.), who established the pietistic principle of Sufism, which may be compared to the Christian emotional principle of faith.

With reference to the head of Islam, Sunnism still as ever lacks a definite principle. When the caliphate of Bagdad came to an end in 1258, one of the Abbasids fled to Cairo and was recognized by Sultan Bibars as caliph under the name of al Mustansir. His descendants continued to hold the power of investing the Mamluk rulers with their authority. The last of these, Muta-wakkīt II, went with Selim I to Constantinople. At some time between 1522 and his death in 1538 he assigned his spiritual power and office to Suleiman II. Hence the Ottoman sultans claim the caliphate. But the fiction is so apparent that it is not universally recognized. It was never acknowledged in Morocco. Sunnism is not bound to the dynasty at Constantinople. Contrary, therefore, to the original theocratic

constitution of Mohammed there has arisen a division between the spiritual and the political forces. Political power is wielded by the Sultan, but the spiritual rule is in the hands of the Ulema (q.v.) of Constantinople, a close corporation of lawyer theologians. Its chief, the Sheik el Islam, is appointed by the Sultan, but only out of that body, and he possesses large independent powers which the Sultan dare not invade. He is the chief spiritual person in orthodox Islam.

Within the Sunnite body exist four different schools of law, those respectively of the Hanbalites, the Hanafites, the Shafites, and the Malikites (so named after their respective founders). The first code is recognized by the Wahabites (see WAHABIS); the second in Upper Egypt and north Africa; the third in Lower Egypt, southern India, and Malaysia; the fourth by the Turks and the Moslems of Central and northern Asia. These schools arose in the second and third centuries of the Hejira and represent so many different compositions between tradition and progressive law. They are at peace with one another now, and divide orthodox Islam among themselves, each people being allowed to live by its law, and each lawyer electing his choice. But in the Ottoman Empire there exists the contrast between this canon law and the secular law. The latter proceeds from the authority of the Sultan or is the ancient secular law of the land; the other, the religious law, is confined mostly to domestic matters, and it is one of the grievances of the orthodox that the legal authority of the religious community is thus put into abeyance by the secular arm. Here again the analogy may be drawn with the dispute which has prevailed in European Christendom between the canon and the civil law. Therefore, both in its past history and in its present condition, Sunnism is by no means to be regarded as a homogeneous body or practice. For literature, see MOHAMMEDANISM; MOHAMMEDAN SECTS.

**SUNNYSIDE**. A gabled stone house on the Hudson River near Irvington, N. Y., noted as the home of Washington Irving, and described in Irving's sketch entitled *Wolfert's Roost*.

**SUN SPOTS**. The name given to a phenomena consisting of variable dark spots upon the solar surface. Sun spots are treated at length under SUN. See TERRESTRIAL MAGNETISM.

**SUNSTONE**, or HELIOLITE. A variety of aventurine, oligoclase, or feldspar, which when polished yields internal yellowish or reddish reflections emanating from crystals or flakes of iron oxide that are contained in the mass. The finest specimens, which show a brilliant play of colors, are found in Norway, although gem varieties occur in the United States at Crown Point, N. Y., and Media, Pa.

**SUNSTROKE**. See HEAT STROKE.

**SUN WORSHIP**. See NATURE WORSHIP.

**SUN YAT-SEN**, sŏn' yăt-sĕn' (1866-1925). A famous Chinese revolutionary leader. He was born at Fatshan, near Canton. His parents took him as a boy to Hawaii, where he attended Iolani College. Later he graduated from the Hongkong School of Medicine, now part of Hongkong University (1892). For a year he practiced at Macao. Afterward he gave himself wholly to the project of driving the Manchu dynasty from China. As early as 1895 he attempted a revolt at Canton, which failed, and Sun alone succeeded in escaping. He fled to

Kobe, Japan, and later to Honolulu and San Francisco. He was soon active the world over in organizing and educating Chinese abroad for his *Kao Lao Hwei*, or reform associations, and in raising and sending money to his agents in China, particularly General Hwang-hsing, for the coming Revolution. He was in constant danger of his life at this time because of the hostility of the Manchu government, and a reward of \$50,000 was offered for his death. Finally the Revolution broke out in China in the fall of 1911, and was successful mainly because of the work of Dr. Sun in the years of preparation. He received his reward in his election as Provisional President of the Chinese Republic by the Assembly at Nanking. On Feb. 15, 1912, Dr. Sun resigned as President in favor of Yuan Shih-kai (q.v.), so as to induce the latter and his north China adherents to join the Republican cause. For this act Sun received a remarkable tribute from the Nanking Assembly. Difficulties in the new Republic soon arose from the opposition of the *Kuomintang* (the south China party of Sun and Hwang-hsing) in the Parliament at Peking to the policy of President Yuan Shih-kai. Yuan finally expelled these members and later dismissed the entire Parliament. Dr. Sun retired to Japan, but it was believed that his continued active opposition to Yuan Shih-kai was shown in the rebellion of July, 1913, and in the revolt of the southern provinces in 1915-16. Consult: E. N. Bland, *Recent Events and Present Policies in China* (Philadelphia, 1912); Cantlie and Jones, *Sun Yat-Sen and the Awakening of China* (3d ed., New York, 1913); J. S. Thomson, *China Revolutionized* (Indianapolis, 1913). See CHINA, *Modern History*.

**SUOVETAURILIA** (Lat., sacrifice of a boar, a sheep, and a bull, from *sus*, boar + *ovis*, sheep + *taurus*, bull). A Roman sacrifice of a boar, a ram, and a bullock, which was offered to Mars, in the lustrum, or purification of the people, on the Campus Martius at the Census, the Ambarvalia in May, the Amburbium in February, and other similar lustrations.

**SUPAI**, sŏo'pĭ. See HAVASUPI.

**SUPAN**, sŏo'pĕn, ALEXANDER (1847-1920). An Austrian geographer, born at Innichen, Tirol. Having studied at the universities of Graz, Vienna, Halle, and Leipzig, and taught at Laibach, he qualified as privatdocent at Czernowitz, Bukowina, and was made professor in 1880, but removed to Gotha in 1884 to assume the redaction of *Petermanns Mitteilungen*. The publication of its geographical literary reports, from 1885, is due to his initiative. He became a member of the International Polar Commission. He wrote: *Grundzüge der physischen Erdkunde* (1884; 4th ed., 1907); *Geographie von Oesterreich-Ungarn* (1889); *Deutsche Schulgeographie* (6th ed., 1903); and numerous contributions to the *Mitteilungen*.

**SUPEREROGATION**, WORKS OF (Lat. *supererogatio*, payment in addition). A class of good works which, in the Roman Catholic system, are described as not absolutely required as conditions to eternal salvation. Roman Catholics found this definition on the distinction between what they believe to be commanded and what they hold to be only counseled. (See EVANGELICAL COUNSELS.) For works of supererogation, as for all supernaturally good works, they hold that the assistance of God's grace is necessary; and they do not ascribe to them any

merit, except that which arises from God's own free promise. A further consequence of this doctrine is that God may accept the superabundant works of one in atonement for the defective service of another; and hence, in the Catholic theory of indulgences (q.v.), along with what they regard as the infinite and inexhaustible treasure of the merits of Christ, they also regard, although in a degree infinitely inferior, the superabundant merits of the saints as forming part of that treasure of the church which is applied in the form of indulgences. The idea of such works is rejected by Protestants generally.

**SUPERFICIES**, sū'pēr-fīsh'ī-ēz (Lat., surface). At civil law, the hereditary and alienable right to maintain and use a building on land belonging to another. Unless a term be fixed in the contract, the right is perpetual. The owner of the land is technically owner of the building (*superficies solo cedit*); but practically the owner has no right except to an annual ground rent (*solarium*). Even when the ground rent has not been paid for several years, the right of the superficiary is not forfeited unless this be expressed in the contract. In the absence of such express agreement, the owner of the land can only attach and sell the superficiary right.

Historically, superficies was first established at Rome in public or municipal land. It was originally in the nature of a lease (*locatio conductio*), but it soon became a different thing, because the superficiary was recognized as having a possessory right (see POSSESSION) and could maintain actions *in rem*—advantages which the Roman lessee did not enjoy. In the later development of the Roman law superficiary right could be established on private land and also in a special story or floor of a building.

Superficies is analogous to emphyteusis (q.v.), but the rights of the superficiary are greater than those of the emphyteutist.

Medieval jurists regarded superficies and emphyteusis as cases of divided ownership, analogous to the feudal tenures. The landlord had *dominium directum*, the tenant *dominium utile*. Some of the modern legislations recognize divided ownership in a different sense: the landlord is said to own the land, the superficiary the house or floor. See DOMINIUM; EMPHYTEUSIS; PROPERTY.

**SUPERFETATION** (from Lat. *superfœtare*, to conceive anew when already pregnant, from *super*, above, over + *fœtare*, to breed, from *fœtus*, offspring), and **SUPERFECUNDATION**. The circumstance of two distinct conceptions occurring in the same woman at an interval of weeks or months, so that two fetuses of different ages, and possibly the offspring of different fathers, may coexist in the uterus. True superfetation takes place when a second ovule has been impregnated while the uterus already contains an ovum which has arrived at a considerable degree of development. By superfecundation is meant the impregnation, at or near the same period of time, of two separate ovules before the decidua lining of the uterus has been formed—believed by many to interpose an insuperable obstacle to subsequent impregnation. The possibility of this occurrence has been proved on occasion by the birth of twins bearing the stamp of fathers of different races, i.e., white and black. The question of superfetation has given rise to much discussion, owing to its medico-legal im-

portance. Against the possibility of this occurrence it is urged that ovulation is suspended when impregnation has taken place; that the decidua (afterbirth) so completely fills the uterine cavity that the passage of spermatozoa is impossible, and that their ascent is prevented by the mucus filling the cervix. It is now believed that none of these obstacles is insuperable.

The medico-legal aspect of the question may be summed up as follows: A woman may be unjustly suspected of conjugal infidelity when, delivery of a mature or premature child having taken place, she is (without having meanwhile seen her husband, or submitted to coitus), in the course of one, two, or three months, delivered of another child, either mature or premature. Cases of this kind may be explained, as indicated above, by twin pregnancy with expulsion of the fetuses at an interval of several weeks or months; by the existence of bilobed uterus, the two cavities expelling their contents at different times; or by true superfetation. When the children are of different race or color the fidelity of the female may be justly questioned. Consult: W. S. Playfair, *Treatise on the Science and Practice of Midwifery* (7th Amer. ed., Philadelphia, 1898); J. J. Reese, *Textbook of Medical Jurisprudence and Toxicology* (8th ed., ib., 1911); W. R. Smith, *Medical Jurisprudence* (London, 1913).

**SUPERHEATER; SUPERHEATED STEAM.** See STEAM; STEAM ENGINE; SHIP-BUILDING, *Machinery*.

**SUPERIOR.** A city, port of entry, and the county seat of Douglas Co., Wis., adjacent to Duluth, Minn.; at the mouth of the St. Louis and Necedji rivers, on three bays, inlets of Lake Superior, and on the Northern Pacific, the Duluth, South Shore and Atlantic, the Great Northern, the Chicago, Milwaukee and St. Paul, the Minneapolis, St. Paul, and Sault Ste. Marie, and the Chicago and Northwestern railroads (Map: Wisconsin, A 2). It is connected with Duluth by two railroad bridges and by a ferry. The city is the seat of a State Normal School, and among other features are a public library and St. Mary's Hospital. An excellent harbor, which has been enlarged and improved through national, State, and city appropriations, and good transportation facilities have contributed to Superior's commercial importance. In the year ending June 30, 1913, the total foreign trade was valued at \$5,178,879, including exports to the amount of \$4,785,986. (See DULUTH.) Wheat, corn, flour, lard, and other meat products, iron and steel, cement, and lumber compose the principal shipments. The various industries, according to the 1914 census, had an invested capital of \$7,050,000, and a production valued at \$11,663,000. There are lumber mills, foundries and machine shops, breweries, flour mills, boiler shops, iron works, manufactories of chairs and windmills, and shipbuilding.

Superior has adopted the commission form of government. For maintenance and operation, the city spent in 1913, \$537,204, the chief items being: schools, \$201,000; fire department, \$96,000; police department, \$48,000; and streets, \$73,000. Pop., 1900, 31,091; 1910, 40,384; 1915 (U. S. est.), 45,285; 1920, 39,624.

On the site of Superior Radisson and Grosseilliers are supposed to have made their headquarters in 1661. Here in 1680 the famous explorer Du L'Hut established a trading post. Superior was first laid out in 1885.

**SUPERIOR, LAKE.** The largest and most northerly of the Great Lakes of North America, and the largest body of fresh water in the world (Map: America, North, K 5). It is situated a little to the northeast of the centre of the continent; its north shores are in Minnesota and the Canadian Province of Ontario, and its south shores in Michigan and Wisconsin. Its shape is nearly crescent, the horns extending southwest and southeast, while the large Keweenaw Peninsula reaches nearly to the centre of the lake from the middle of the southern coast. Lake Superior has a coast line of 1500 miles; its extreme length from east to west is 412 miles; its extreme breadth 167. Area, 31,200 square miles. Its mean elevation above sea level is 602 feet, and it lies 20 feet above Lake Huron, into which it discharges through the St. Mary's River (q.v.). It receives a large number of streams, but they are short, the basin of the lake being hemmed in by the watersheds of the Mississippi and of Hudson Bay. The principal stream entering it is the St. Louis River, which falls into the extreme west end of the lake, and is considered the farthest head stream of the St. Lawrence.

The shores of Lake Superior, except in the southeast, where there are sand dunes, are generally bold and rocky. On the Michigan shore are the celebrated sandstone cliffs known as Pictured Rocks, which are streaked by the red and yellow deposits of ferruginous waters. In many places, especially along the Canadian shore, there are precipitous cliffs of basalt rising directly from the water to a sheer height of from 300 to over 1000 feet, such as Thunder Cape on the northwest shore. The north shore is cut into deep bays surrounded by high cliffs, and forming good harbors, and it is lined with a number of high, rocky islands. In the greater part of the lake, however, the islands are few, the largest being Isle Royal, 45 miles long and 8 miles wide, belonging to Michigan. In general the country surrounding the lake is covered with pine forests.

Lake Superior is deeper than any of the other Great Lakes, its maximum depth being 1008 feet, so that the bottom lies 400 feet below sea level. The water is very clear, and so fresh as to be almost chemically pure. It is cold throughout the year to within a few feet of the surface, and in the deeper portions maintains a nearly uniform temperature of 39° F. The lake never freezes except in shallow water along the shores. The water level is subject to several sets of periodic changes, partly owing to changes in rainfall and evaporation and partly to the winds; a continued storm will sometimes raise the leeward level seven feet above the normal. Violent storms occasionally sweep over the lake, when waves may rise to about 15 or 18 feet.

The basin of Lake Superior is remarkable as being unrelated to those of the other Great Lakes. While the latter are river valleys scooped out of the softer strata of the ancient coastal plain lying northwest of the Appalachian plateau and skirting the Archean continent, Lake Superior lies almost wholly within the Archean region. The most recent investigators are of the opinion that this basin is in the western part, at least, a rift valley produced by graben faulting in the Superior upland. These uplands are a part of an extensive penepain which truncates Archean and Algonkian igneous, sedimentary, and metamorphic rocks. The

formation of the lakes themselves, however, is due to the obstruction of the valleys during the Glacial period. The country surrounding the lake is rich in minerals, and large veins of copper and iron ore traverse its bottom from the southern shore. Consult Agassiz, *Lake Superior: Its Physical Character, Vegetation, and Animals* (Boston, 1850), and Martin, "Progressive Development of Resources in the Lake Superior Region," in *American Geographical Society*, vol. xliii (New York, 1911). For commerce and navigation on the lake, see GREAT LAKES.

**SUPERPHOSPHATE.** An orthophosphate in which only a portion of the hydrogen of the orthophosphoric acid has been replaced by a basic radical. The most important superphosphate, agriculturally, that of lime, monocalcium phosphate ( $\text{CaO} \cdot 2\text{H}_2\text{O} \cdot \text{P}_2\text{O}_5$ ), is prepared by treating tricalcium phosphate ( $3\text{CaO} \cdot \text{P}_2\text{O}_5$ ) in the form of mineral phosphate, bone ash, bone black, etc., with sulphuric acid. It is also called acid phosphate. See MANURES AND MANURING.

**SUPERPOSITION.** See CONGRUENCE.

**SUPERPOSITION.** In architecture the systematic disposition of one feature or set of features or members over another; especially, in the classic and neoclassic styles, of one order over another. See ORDERS OF ARCHITECTURE; ROMAN ART.

**SUPERSEDEAS** (Lat., that you set aside).

A common-law writ containing an order for a stay or suspension of legal proceedings. Under the common-law practice it is issued in a great variety of cases for the above purpose, and is sometimes used as a substitute for the common-law writ of *audita querela* (q.v.). Probably it is issued most frequently to stay execution, pending an appeal from a judgment. The person applying for the writ is required to give a bond to secure the other party against loss by reason of the delay. Several writs are said to operate as a supersedeas by implication, as in effect they operate as a stay, viz.: habeas corpus, certiorari, and writ of error. The practice of granting a stay by an order of the court has superseded the above practice in many jurisdictions.

**SUPERSTITION** (Lat. *superstitio*, excessive religious belief, superstition, possibly originally a standing over a thing in amazement or awe, from *superstare*, to stand above or over, from *super*, above, over + *stare*, to stand). This is a catchword currently employed to designate beliefs and usages not consonant with accepted notions of reality and possibility. Ethnologically the term is meaningless because from the point of view of this science our own conception of truth and possibility is but one of an indefinite number of such conceptions, just as from the modern geometrician's position three-dimensional space is but one of an indefinite number of mathematically tenable spaces. It might be argued that the modern Weltanschauung of Europe and America is distinguished from all others by its predominantly rationalistic character. But this would apply at best solely to the scientific portion of our cultural stock in trade, while our religious doctrines, our ethical and our æsthetic principles are conceivably, and indeed partly in fact, a matter of contempt and even horror to members of other races. Accordingly, it seems arbitrary and a matter of bias to exalt our own notions of fitness by abasing others to the level of superstitions.

On the other hand, it is entirely proper to

merge superstitions so-called with the ethnological phenomena known as "survivals." It is simply an historical fact that among the ancient Assyrians, and indeed much later, it was part of the official State religion to prophesy as to the future from the flight of birds, the nature of dreams, human and animal abortions, and what not; and that such practices are no longer countenanced by the dominant religious bodies of Europe and America. Hence where such customs and the correlated beliefs persist, they may be regarded as survivals, as vestigial relics from a past when they were in full bloom.

Among these survivals perhaps the most persistent in rural districts is the belief in ghosts, and in the influence of the moon; crops should always be planted so that the increase of the moon will aid their growth, and conversely if it is desired to destroy brush or weeds, it should be done at the full of the moon so that they may shrink as she does. In parts of Europe the malignant and blighting effects of the evil eye are still feared; the caul and in the United States the horseshoe are still accepted, seriously or otherwise, as emblems of good luck. As examples of the many methods of divination, a few of which still survive, may be mentioned aëromancy, or divination by appearances in the air; alectromancy, by a fowl picking up grains of wheat; aleuromancy, by wheat; axinomancy, by the axe or hatchet; belomancy, by means of arrows; bibliomancy, by the Bible; cartomancy, by playing cards; capnomancy, by smoke from an altar; catoptromancy, by mirrors; chiromancy, by the hand; cledonismancy, by certain lucky or unlucky words; clidomancy, by keys; coscinomancy, by sieves; dactylomancy, by suspended rings; gastromancy, by ventriloquism, or by a vial of water; geomancy, by geometrical figures; gyromancy, by walking in a circle; lithomancy, by precious stones, or pebbles; myomancy, by mice; onomancy, by letters forming the name of a person.

It is necessary to emphasize here that while there has been a demonstrable elimination of irrational elements, the rational elements of human nature are still so much weaker than the emotional that there is a constant danger for the springing up of new beliefs and practices with an irrational foundation. Even the provisional results of science, when interpreted as doctrines of absolute validity, degenerate into dogmas, so that modern critics are justified in speaking of a mechanistic and evolutionary mythology. See FOLKLORE; MAGIC; MAN, SCIENCE OF; MYTHOLOGY; RELIGION, COMPARATIVE.

**SUPERVISOR** (ML. *supervisor*, overseer, from Lat. *super**videre*, to overlook, oversee, from *super*, above, over + *videre*, to see). A popularly elected officer of a township or other local district in the United States. The name first appeared in New York in 1691. This officer is still the chief administrator of the town organization in New York, while all the supervisors of the county assembled in a board meeting constitute the chief county authority. The New York supervisor system exists in several Western States. In Michigan and Illinois, as in New York, there is a single supervisor for each township, while in Wisconsin and Minnesota there are three for each township. In some States the supervisor is not a member of the county board and his duties vary, as, e.g., in Michigan, where he is also tax assessor, and

in Illinois, treasurer. See UNITED STATES, section on *Local Government*.

**SUPPÉ**, zup'pâ, FRANZ VON (1820-95). An Austrian composer of light opera, born at Spalato, Dalmatia. He studied at the Vienna Conservatory under Sechter and Seyfried. He was kapellmeister successively at the Josephstädter Theater, the Theater an der Wien, and from 1865 until the end of his career at the Leopoldstädter Theater. He was a prolific composer; the most important of his works include the operettas *Flotte Bursche* (1863); *Die schöne Galathea* (1865); *Leichte Kavallerie* (1866); *Banditenstreiche* (1867); *Fatinitza* (Vienna, 1876); *Boccaccio* (1879); *Das Modell* (posthumously, 1895). He also composed considerable instrumental and sacred music. He was one of the most popular and important of the world's light opera composers, and a musician of no little genius. Consult O. Keller, *Franz von Suppé, der Schöpfer der deutschen Operette* (Leipzig, 1905).

**SUPPLE-JACK'** (*Berchemia scandens*). An American twining shrub of the family Rhamnaceæ, which is found as far north as the Dismal Swamp in Virginia. It has oval leaves, small flowers, and violet-colored berries, and ascends to the top of the highest trees. The name is also given in the West Indies and tropical America to *Serjania lucida* and *Serjania trachygona*, shrubs of similar habit which belong to the family Sapindaceæ. The stems are used for walking sticks.

**SUPPLEMENTARY PROCEEDINGS**. Certain proceedings under codes and practice acts designed to discover property of a judgment debtor and apply it to the satisfaction of the judgment. Before such proceedings can be instituted execution in the judgment must be issued and returned wholly or partly unsatisfied. The order directs the debtor to appear and submit to an examination under oath as to his property. When the judgment creditor has reason to believe that there is property in the possession of third parties to which the judgment debtor is entitled, an order may be obtained for the examination of the third party. Most acts provide for the appointment of a receiver where property is found. Consult *New York Code of Civil Procedure*. See EXECUTION.

**SUPPLIANTS**, THE (Lat. *Supplices*, Gk. *Ἰκέτιδες*, *Hiketides*). 1. The earliest of the extant plays of Æschylus, of uncertain date. With but slight plot or dramatic action it pictures the arrival of the 50 daughters of Danaüs on the shore near Argos, their prayer to the King of Argos for protection, the appearance of the ship bearing the 50 sons of Ægyptus, and their repulse by the King.

2. A tragedy by Euripides, produced about 420 B.C. Theseus and the Athenians, entreated by the mothers of the dead chiefs, after defeating the Thebans, oblige them to surrender the bodies of the slain Polynices and his allies, to whom they had refused burial. The funeral of the chiefs, the burning of Evadne on the pyre of her husband, Capaneus, and the patriotic and political references provide the interest lacking in the simple plot.

**SUPPLY**. See DEMAND AND SUPPLY.

**SUPPORTERS** (from Lat. *supportare*, *sub-portare*, to support, from *sub*, under + *portare*, to carry). In heraldry, figures placed on each side of an armorial shield. See HERALDRY.

**SUPPOSITORY** (Lat. *suppositorium*, from

*supponere, subponere*, to put beneath, from *sub*, under + *ponere*, to put, place). A solid medicated compound intended to be introduced into the rectum, vagina, or urethra, either for the purpose of causing an evacuation of the bowels, or for its specific effect on inflamed mucous membrane. Suppositories are made in several shapes—conical, cylindrical, or spherical—and in sizes adapted to the orifice they are intended to enter. In consistency they are such that they remain solid at ordinary temperatures, but melt slowly at the temperature of the body. The basis of most suppositories is cocoa butter. With this are incorporated one or several ingredients, such as glycerin, carbolic acid, tannic acid, belladonna, morphine, opium, cocaine, and ichthyol.

**SUPPURATION** (Lat. *suppurare, subpurare*, to form pus, from *sub*, under + *pus*, matter from a sore). A morbid process which takes place in animal tissues, resulting in the formation of pus. It is a frequent termination of inflammatory processes and is due to invasion of the inflamed tissues and their exudates by pyogenic organisms. (See **PUS**; **INFLAMMATION**.) White blood cells escape into the neighboring tissue after passing through the walls of the blood vessels, and become pus cells. If they escape to the surface and there is an open wound, the wound is said to suppurate. If they are confined to a circumscribed area below the surface, the collection of pus cells and broken down tissue is called an abscess (q.v.). See **ABSCESS**.

**SUPRALAPSARIAN**. See **INFRALAPSARIAN**.

**SUPRARENAL** (from Lat. *supra*, above + *renalis*, relating to the kidneys, from *renes*, kidneys) **CAPSULES**. The suprarenal capsules are two small, flattened, glandular bodies of a yellowish color and crescentic shape, situated, as their name implies, immediately in front of the upper end of each kidney. They are also called the suprarenal bodies or the adrenals. The suprarenal bodies are subject to inflammation, to atrophy, and to invasion by malignant processes, but all of these occurrences are extremely rare. The only morbid process that occurs with any frequency is tuberculosis. This process is the causative factor in the production of Addison's disease (q.v.), a rather rare and usually fatal affection characterized by anæmia, languor, feebleness of the heart's action, irritability of the stomach, and bronzing of the skin. There are several hæmostatic preparations of the capsules called variously adrenalin, adnephren, epinephrin, suprarenin, suprarenalin, etc. These suprarenal extracts are used largely in eye, nose, and throat surgery, to control bleeding, in locally applied dilutions of one in 5000 or 10,000 parts of normal salt solution. Internally they are of value in hæmophilia, tuberculosis with hemorrhages, pneumonia, and asthma. The dried and prepared suprarenal substance of animals constitutes a powerful and valuable astringent and hæmostatic. See **ORGANOTHERAPY**; **SECRETIONS**, *Internal*.

**SUPRARENAL EXTRACT**. See **SUPRARENAL CAPSULES**.

**SUPREMACY**, **ROYAL** (Lat. *supremus*, highest, superlative of *superus*, high). A phrase specifically applied to the relation of the sovereign of England to the established church of that country. During the Reformation the supremacy of the Pope was abolished in England, and the Act passed in 1534 declared the King to be the "only supreme head on earth of the

Church of England." The government at the same time explained that the intention was merely to recognize in the sovereign a governor without spiritual jurisdiction, and not to "take any power from the successors of the Apostles that was given them by God." Under Queen Mary this Act of Supremacy was repealed in 1554, but this repeal was itself repealed by Queen Elizabeth in 1559, who, however, did not make use of the words "supreme head." In her injunctions she explained the supremacy of the crown to be "that which is and was of ancient time due to the Imperial crown of this realm, i.e., under God to have the sovereignty and rule over all manner of persons born within those her realms of what estate either ecclesiastical or temporal soever they may be so as no other foreign power shall or ought to have any superiority over them." The governing and visitatorial power of the sovereign, under the safeguard of an organized court of justice, has since been continuously recognized by the Church of England. By successive statutes an oath as to royal supremacy was appointed to be taken by the holders of public offices along with the oaths of allegiance and abjuration. A royal supremacy similar in character is a prerogative of the Czar of all the Russias, also of the Protestant princes of Germany, and of the sovereigns of Holland, Denmark, Norway, and Sweden.

**SUPREME COURT**. In Great Britain the Supreme Court of Judicature was constituted in the year 1873. It is a court founded upon the consolidation of the High Court of Chancery in England, the Court of Queen's Bench, the Court of Common Pleas at Westminster, the Court of Exchequer, the High Court of Admiralty, the Court of Probate, the Court for Divorce and Matrimonial Causes, and the London Court of Bankruptcy. The Supreme Court is divided into two permanent divisions, His Majesty's High Court of Justice and His Majesty's Court of Appeal. The High Court in turn is now divided into three subdivisions, viz., the Chancery Division, the King's Bench Division, and the Probate, Divorce, and Admiralty Division. The judges of the High Court are the Lord Chancellor, the Lord Chief Justice of England, the Master of the Rolls, the President of the Probate, Divorce, and Admiralty Division, and twenty-two puisne judges. The Court of Appeal consists of the Lord Chancellor, who presides over the court, the Lord Chief Justice of England, the Master of the Rolls, the President of the Probate, Divorce, and Admiralty Division (these acting *ex officio*), and five Lords Justices of Appeal. This court usually sits in two divisions, one of which hears appeals from the King's Bench and Probate, Divorce, and Admiralty Divisions, and the other from the Chancery Division. See **COURT**.

**SUPREME COURT, MASTER OF THE**. See **MASTER OF THE SUPREME COURT**.

**SUPREME COURT OF THE UNITED STATES, THE**. The Supreme Court of the United States is the head of the national judiciary. Art. III, Sec. 1 of the Constitution provides that "the judicial power of the United States shall be vested in one Supreme Court, and in such inferior courts as the Congress may from time to time ordain and establish." The Supreme Court is thus a constitutional court, while the others are statutory. Though the Constitution provides for a Supreme Court, it leaves its organization and membership for con-

gressional supervision. The first Act in respect thereto was passed at the first session of the United States Congress, approved by President Washington Sept. 24, 1789; it directed that the court should consist of a Chief Justice and five associate justices, any four of whom should make a quorum. This act not only made provision for the Supreme Court, but created the inferior courts of the United States and organized its entire judicial system.

The Constitution (Art. III, Sec. 2) declares that "the judicial power shall extend to all cases, in law and equity, arising under this Constitution, the laws of the United States, and treaties made, or which shall be made, under their authority; to all cases affecting ambassadors, other public ministers, and consuls; to all cases of admiralty and maritime jurisdiction; to controversies to which the United States shall be a party; to controversies between two or more States; between a State and citizens of another State; between citizens of different States; between citizens of the same State claiming lands under grants of different States, and between a State, or the citizens thereof, and foreign States, citizens, or subjects." And also that "in all cases affecting ambassadors, other public ministers, and consuls, and those in which a State shall be party, the Supreme Court shall have original jurisdiction. In all the other cases before mentioned, the Supreme Court shall have appellate jurisdiction, both as to law and fact, with such exceptions and under such regulations as the Congress shall make." The original jurisdiction, conferred by the Constitution, cannot be taken away by Congress, although that body may prescribe the procedure by which that jurisdiction is to be exercised; but in respect to the appellate jurisdiction both the procedure and its extent are matters of congressional determination, and Congress has at times made changes in each.

The appellate jurisdiction may be separated into two divisions: one over State courts; the other over the inferior Federal courts. With respect to the former the Supreme Court reviews the final judgment rendered in any case by the highest court of the State to which the case under State practice can be carried. Up to 1891 it had, generally, jurisdiction to review the proceedings in any case which had passed to final judgment in such inferior courts, with a limitation in some cases to a certain amount in controversy. By the Act of 1891 courts of appeal were established, one in each circuit, and were given final jurisdiction in certain cases, such as revenue, admiralty, patent, etc. But the Supreme Court may still by certiorari, if it sees fit, bring any of these cases from a court of appeals before it for review. This Act did away with the limitation as to amount in controversy. In addition the Supreme Court is given power to issue writs of prohibition and all other writs necessary for the exercise of its jurisdiction and agreeable to the principles and usages of law. Thus the Supreme Court has complete supervision and control over all the inferior courts of the United States.

Early there arose two parties in the country: one believing that the new government was but a continuance of the old confederacy—a league of States, the States remaining dominant, and the national government serving only as a limited agency for transacting matters of general importance: the other that a new nation was

created, supreme, with powers of a nation, the States being simply parts. By one party the provisions of the Constitution were strictly construed (see STRICT CONSTRUCTIONISTS), no power was vested in the national government except that expressly named. The other believed the Constitution was to be so construed as to give vigor and efficiency to the nation. The question was finally settled by the Supreme Court, which has always spoken for the nationality of the United States. A brief reference to some of the leading cases may indicate its action, and the effect thereof. In *Chisholm, executor, v. Georgia*, 2 Dall. 419, decided Feb. 18, 1793, the court (considering those provisions of the Constitution which extend the judicial power of the United States to controversies "between a State and citizens of another State," and give to the Supreme Court original jurisdiction of controversies to which a State is a party) held that an action might be maintained against a State by a citizen of another State. The national idea was not yet strong, and the proposition that a sovereign State could at the instance of an individual and without its consent be brought to the bar of a court and compelled to defend an action against it startled many. As a consequence the Eleventh Amendment was adopted, which in effect forbids an action in the Federal courts against a State by an individual.

John Marshall became Chief Justice in January, 1801, and remained in office for 34 years. It was a great constructive period, and by those decisions which declared the relative powers of the nation and the State was disclosed the full significance of the Constitution as an instrument expressing the creating of a new nation and not an article of confederation between States. Not merely were these relative powers declared, but the value of the Supreme Court in determining the extent of such relative powers and to pass upon acts of State and nation were made apparent. In *Marbury v. Madison*, 1 Cranch, 137, decided Feb. 24, 1803, it was held that an Act of Congress repugnant to the Constitution was void and that it was the function of the court to ascertain in cases properly before it whether such repugnancy exists. This power of the courts though often criticized, especially in recent years, has never been shaken. According to an estimate made by Dr. Blaine F. Moore, the Supreme Court between 1790 and 1912 declared unconstitutional 33 statutes of Congress, 223 State statutes and 23 municipal ordinances. In the same period there were 185 decisions sustaining statutes of Congress, 646 sustaining State statutes, and 73 sustaining municipal ordinances.

The next important decision following *Marbury v. Madison* was *M'Culloch v. Maryland*, 4 Wheat. 316, in which the question was presented of the power of Congress to charter a national bank. The Constitution gives in terms no such power, or any power to create corporations, and advocates of strict construction contended that Congress could not create a corporation for any purpose. The court, upon the authority of that clause which, following the clauses making express grants to Congress, empowers that body to "make all laws which shall be necessary and proper for carrying into execution the foregoing powers," held that, as a bank was a proper and convenient agency for carrying on the fiscal affairs of a government, there was power in Congress to create a banking cor-

poration; that the word "necessary" was not to be construed in a strict and narrow sense, but—viewing the Constitution as an organic instrument, which from the very necessities of the case used general terms in giving to that government the power essential for its being—to be taken broadly and liberally, and declared what has become axiomatic in constitutional law: "Let the end be legitimate, let it be within the scope of the Constitution, and all means which are appropriate, which are plainly adapted to that end, which are not prohibited, but consistent with the letter and spirit of the Constitution, are constitutional."

This decision laid the foundation of what is known as the doctrine of implied powers, well appreciated when we recall that under a grant of power stated in the few words "to establish post offices and post roads" the great postal system of the United States has been built up. At the same time was decided the case of the Trustees of Dartmouth College *v.* Woodward, 4 Wheat. 518, in which it was held that the charter of a private corporation granted by a State created a contract whose obligations the State could not impair, because of that provision of the Federal Constitution which forbids a State to pass any law "impairing the obligation of contracts." (See *DARTMOUTH COLLEGE CASE*.) Popular disapproval of this decision is indicated by the fact that practically all of the States subsequently enacted amendments to their constitutions reserving the power of repeal, alteration, and amendment of all corporate grants.

*Martin v. Hunter*, 1 Wheat. 304, and *Cohens v. Virginia*, 6 Wheat. 264, the latter decided at the February term, 1821, settled the power of the Supreme Court to review, and if necessary set aside, the proceedings of a State court in a case in which a Federal right was asserted by the defeated party. Again, in *Gibbons v. Ogden*, 9 Wheat. 1, decided in 1824, the supreme power of the Federal government over the navigable waters of the United States was affirmed. In that case Robert Fulton, the inventor of the steamboat, and his associate, Robert R. Livingston, obtained from the State of New York the grant of an exclusive right to navigate with steamboats the waters within the jurisdiction of that State. Gibbons claimed a right under national authority to navigate with his steamboats the same waters, and hence the litigation. The Constitution having granted to Congress the power to "regulate commerce with foreign nations and among the several States," it was held that that power could not be infringed upon by any action of a State and that a State could not interfere with such commerce even when carried upon waters wholly within its own territory. Upon that decision rests freedom of commerce between the States. In this connection the case of "*The Genesee Chief*," 12 How. 443, decided in 1851, may be noticed. In that case it was held that the English rule that the jurisdiction of admiralty ended with tide waters was inapplicable, and that in the United States such jurisdiction, which by the Constitution is vested in the Federal courts, extends to all the navigable waters of the Republic. Thus the control of the Great Lakes and all the navigable rivers of the United States, whether within or without the limits of a State, is vested in the national government. In *Osborn v. United States Bank*, 9 Wheat. 738, it was held that a State had no power to tax one of the branches

of the United States Bank; that the bank was one of the agencies and instrumentalities of the national government, removed from the sphere of State taxation. From that decision comes the rule exempting all agencies and instrumentalities of the national government from State taxation except so far as permitted by Congress. This is seen in respect to United States bonds, national banks, etc. Conversely, later, in *The Collector v. Day*, 11 Wall. 113, decided December, 1870, it was held that Congress could not impose an income tax on the salaries paid to State officials.

Chief Justice Marshall was succeeded by Chief Justice Taney, a strict constructionist. But the court still affirmed the nationality of the United States. In *Ableman v. Booth*, decided in 1858, 21 How. 506, a prisoner in custody of the United States authorities was held not to be subject to discharge by State process. In the "*Dred Scott Case*," decided in 1856, 19 How. 393, the nationality of the United States was asserted, though not satisfactorily to the friends of human freedom, in that it decided that the recognition by the Constitution of slave property carried with it the protection of that property in all the territories of the nation.

When the Civil War ended and Chief Justice Taney had been succeeded by Chief Justice Chase a new series of cases arose. Some stringent laws had been passed by Congress and by some States against participants in the rebellion. Test oaths were prescribed which prevented many who had taken part with the South from pursuing their professions, but in *Cummings v. Missouri*, and *ex parte Garland*, decided in 1866, 4 Wall. 277 and 333, such test oaths were adjudged invalid as *ex post facto* acts. At the same time, in *ex parte Milligan*, 4 Wall. 2, it was held that a military tribunal, sitting in Indiana, a State in which there had been no rebellion, had no jurisdiction to punish a citizen, in no way connected with the army, for an offense against the government. In *Texas v. White*, 7 Wall. 700, decided in 1868, it was held that States in rebellion did not lose their existence or identity, Chief Justice Chase making the declaration that this was "an indestructible union composed of indestructible States." Soon after the war the Fourteenth Amendment to the Federal Constitution was adopted, which prohibited the States from depriving any person of life, liberty, or property without due process of law, and from denying to any one the equal protection of the law. It was claimed by many that this operated to prevent the grant by a State of any special privileges, but in the *Slaughter House Cases* (q.v.), 16 Wall. 36 (1872), restrictions on the butchering business in New Orleans were held to be valid. In 1890 came *Leisy v. Hardin*, 135 U. S. 100, a case which held that a State cannot forbid the sale of liquor in original packages imported from other States. This decision and those following it gave rise to Congressional statutes known as the Wilson Act and the Webb-Kenyon Act, as a result of which the States may now exercise effective control over the liquor traffic. In 1895, in the *Income Tax Cases*, 82 U. S. 429, it was held that the constitutional provision requiring direct taxes to be apportioned among the States according to their population rendered invalid a tax which was not so apportioned on incomes derived from real estate and as the direct product of

personal property. This decision led to the passage of the Sixteenth Amendment ratified in 1913 which provides that Congress may levy taxes on incomes without such apportionment among the several States. In the *Insular Cases*, 128 U. S. 1, and succeeding cases arising out of the conquest of Porto Rico and the Philippines, the court considered the power of Congress to govern territories acquired by war or treaty, and affirmed to the largest extent the national power of the Republic, holding that a number of the important limitations on congressional action were not applicable to territory not incorporated by Congress into the United States. During recent years important decisions of the court have dealt with congressional and State regulation of commerce and with laws passed by the States in the exercise of police power. Generally these decisions have sustained the application of previously established principles. The court has tended strongly towards extension of Federal control over interstate commerce and restricting the States in any action which interferes with the freedom of such commerce. It has on the whole been favorable to the rapidly increasing restraints the States have imposed upon individual action for the promotion of the general public welfare.

In 1801, the first year of Chief Justice Marshall's term, only 10 cases were filed in the court; from 1875 to 1880 there were 1953, or about 390 a year. While the Act of 1891 diminished the number of cases that could come to the court, yet 401 cases were filed in 1900 and 383 in 1901. During the October, 1914, term, the court rendered opinions in 272 cases and decided without opinion 222 cases.

As heretofore stated, the court at first consisted of six members; it never has had at any time over 10, and now has but nine. The chief justices and their States have been: John Jay, New York; John Rutledge, South Carolina; Oliver Ellsworth, Connecticut; John Marshall, Virginia; Roger B. Taney, Maryland; Salmon P. Chase, Ohio; Morrison R. Waite, Ohio; Melville W. Fuller, Illinois; Edward D. White, Louisiana. Associate justices: William Cushing, Massachusetts; James Wilson, Pennsylvania; John Blair, Virginia; James Iredell, North Carolina; Thomas Johnson, Maryland; William Paterson, New Jersey; Samuel Chase, Maryland; Bushrod Washington, Virginia; Alfred Moore, North Carolina; William Johnson, South Carolina; Brockholst Livingston, New York; Thomas Todd, Kentucky; Joseph Story, Massachusetts; Gabriel Duval, Maryland; Smith Thompson, New York; Robert Trimble, Kentucky; John McLean, Ohio; Henry Baldwin, Pennsylvania; James M. Wayne, Georgia; Philip P. Barbour, Virginia; John Catron, Tennessee; John McKinley, Alabama; Peter V. Daniel, Virginia; Samuel Nelson, New York; Levi Woodbury, New Hampshire; Robert C. Grier, Pennsylvania; Benjamin R. Curtis, Massachusetts; John A. Campbell, Alabama; Nathan Clifford, Maine; Noah H. Swayne, Ohio; Samuel F. Miller, Iowa; David Davis, Illinois; Stephen J. Field, California; William Strong, Pennsylvania; Joseph P. Bradley, New Jersey; Ward Hunt, New York; John M. Harlan, Kentucky; William B. Woods, Georgia; Stanley Matthews, Ohio; Horace Gray, Massachusetts; Samuel Blatchford, New York; Lucius Q. C. Lamar, Mississippi; David J. Brewer, Kansas; Henry B. Brown, Michigan; George Shiras, Jr., Penn-

sylvania; Howell E. Jackson, Tennessee; Edward D. White, Louisiana; Rufus W. Peckham, New York; Joseph McKenna, California; Oliver W. Holmes, Massachusetts; William R. Day, Ohio; William H. Moody, Massachusetts; Horace H. Lurton, Tennessee; Charles E. Hughes, New York; Willis Van Devanter, Wyoming; Joseph R. Lamar, Georgia; Mahlon Pitney, New Jersey; James C. McReynolds, Tennessee. Consult: B. R. Curtis, *Jurisdiction, Practice, and Peculiar Jurisprudence of the Courts of the United States* (2d ed., Boston, 1896); H. L. Carson, *History of the Supreme Court of the United States, with Biographies of all Justices* (2 vols., Philadelphia, 1902); B. F. Moore, *The Supreme Court and Unconstitutional Legislation* (New York, 1913). See CONSTITUTION OF THE UNITED STATES; COURT; FEDERAL GOVERNMENT.

**SUQUAMISH**, sū-kwōm'ish. See SALISHAN STOCK.

**SURABAYA**, sūr'ā-bā'yā. The most populous residency in Java. Area, 2091 square miles (Map: East Indies, D 7). The soil is fertile and produces an abundance of rice, coffee, sugar cane, indigo, and tobacco. Capital, Surabaya. Pop., 1905, 2,875,091.

**SURABAYA**, or **SOERABAYA**. The largest city in Java, and the capital of the Residency of Surabaya, situated in the eastern part of the north coast, at the mouth of the Brantas River (Map: East Indies, D 7). It has a good harbor and strong fortifications and is the military and naval headquarters of the Dutch East Indies. The houses are generally separated by gardens. Simpang, the suburb, contains the home of the Resident and a large hospital. The shipbuilding industry is important. The trade in rice, coffee, cotton, sugar, tobacco, and coconuts is very extensive. Pop., 1905, 150,198, of whom 8063 were Europeans.

**SURAKARTA**, sūr'ā-kār'tā. A residency in the central part of Java, between Samarang and Surabaya (Map: East Indies, D 7). Area, 2404 square miles. The residency is one of the so-called independent states and is governed by a native emperor, who is subsidized by the Dutch and wholly under their control. Capital, Surakarta. Pop., 1905, 1,621,404.

**SURAKARTA**, or **SOERAKARTA**. The capital of the Residency of Surakarta, Java, on both banks of the Pepé River and on the railway between Samarang and Surabaya (Map: East Indies, D 7). It is the residence of the native prince, whose palace is directly opposite the great fort called Vastenburg in the middle of the city. Pop., 1905, 118,378.

**SURAT**, sūr'āt'. The capital of a district of the same name, Bombay, British India, 166 miles by rail north of Bombay, at the mouth of the Tapti, in the Gulf of Cambay (Map: India, B 5). The town is surrounded on the landward side by a brick wall. It has numerous mosques and several Hindu and Parsi temples and the palace of the former Nawab of Surat. The Tapti, owing to a sand bar, affords entry only to small vessels, and the commerce of Surat, which from the sixteenth century to the eighteenth century was very extensive, has been steadily diverted to Bombay. Surat has a castle dating from 1540, centrally situated on the river front. The city rose into importance as the spot whence the Mohammedans of Hindustan embarked on their pilgrimage to Mecca. In 1612 the English East India Company established a factory here, which for some time was

their principal trading station in India. Pop., 1901, 118,364; 1911, 114,868.

**SURBITON.** A town in Surrey, England, on the Thames, mainly residential, 13 miles southwest of London. Surbiton Common witnessed the last stand of the Royalists in the Civil War. Pop., 1901, 15,019; 1911, 17,717.

**SURDS.** See IRRATIONAL NUMBER.

**SURESNES**, su'rân'. A town of the Department of Seine, France, at the foot of Mont Valérien, on the left bank of the Seine, 7½ miles west of Paris (Map: France, N., A 2). In 1593 a conference was held here which resulted in the adoption of Catholicism by Henry IV. Pop., 1901, 11,225; 1911, 15,765.

**SURETTE**, sŭ-rĕt', THOMAS WHITNEY (1862-). An American organist and composer. He was born in Concord, Mass., and studied music under Arthur Foote and J. K. Paine. In 1883 he became organist in his native town, and in 1894-96 was organist and choirmaster of Christ Church, Baltimore. In 1896 he became interested in the University Extension movement, and devoted most of his time to lecturing under its auspices on musical subjects. His compositions include an operetta, *Priscilla* (1899), an opera, *Cascabel* (1899), a ballad for chorus and orchestra, *The Eve of St. Agnes*. He also wrote *The Development of Symphonic Music* (1915).

**SURETY INSURANCE.** See INSURANCE.

**SURETYSHIP** (from *surety*, from Fr. *sûreté*, from Lat. *securitas*, freedom from care). The engagement by which one person becomes legally bound to another for the liability of a third. It therefore involves three parties: the creditor, the principal debtor, and the surety. The distinction between this term and another which is often used interchangeably with it has been pointed out under GUARANTY (q.v.), and need not be repeated here.

It is generally held that surety agreements are subject to the ordinary rule of interpretation that a written contract is to be construed strongly against the party executing it. This will always be enforced when it appears that the language was chosen by the signer, whether he enters into the contract for his own benefit or for the benefit of a third person. Another important rule is that such contracts shall be interpreted so as to give effect to all of their provisions if possible.

After the contract is made it is the duty of the creditor not to enter into any binding engagement with the principal, modifying that contract, without the assent of the surety. The law favors the surety and protects him with much jealousy. Accordingly, if the creditor varies the terms of the original contract or changes securities put into his hands by the principal debtor, or discharges a cosurety, or gives time to the principal debtor, or negligently causes a loss to the surety, the latter will be discharged unless he has assented to this conduct of the creditor. If, however, the principal debtor or a cosurety is discharged from liability by operation of law, as by a discharge in bankruptcy, the surety still remains bound. In a true instance of suretyship, as distinguished from guaranty, the surety is liable even if the obligation of the principal debtor is void or voidable, as in the case of an infant.

The rights of the surety may be considered under three heads. First: Against the principal debtor. As soon as the debt becomes due, the

surety is entitled to call on him for exoneration. This relief is obtainable in a court having equitable powers, it being unreasonable that the surety should have such a cloud hanging over him. If the surety has been compelled by the creditor to pay the debt, he is entitled to call on the principal for reimbursement; for the money paid by him was paid for the principal's use. Second: Against the creditor. As soon as the debt becomes due the surety may demand that the creditor sue the principal and collect the debt from him. In some of the United States the surety is discharged from liability if the creditor does not sue the principal upon the surety's request. One who is surety for the honesty or good conduct of an employee is entitled to have the employee discharged from service for serious defaults or breaches of duty, or to be freed from his suretyship. As the surety has assumed a primary obligation the creditor may sue him without first exhausting his remedies against the principal debtor, and even a demand on the latter is generally unnecessary. Furthermore, as the obligation is primary it is not a promise to pay the debt, default, or miscarriage of another and hence need not be in writing under the Statute of Frauds. Another and very important right of the surety is to have the benefit of all securities which the creditor holds against the principal. This is known as the right of subrogation (q.v.). Third: Against cosureties. It often happens that one surety is compelled by the creditor to pay the whole debt, and that the debtor is worthless. In such a case the unlucky surety is entitled to call upon his cosureties for contribution. Consult authorities cited under GUARANTY. See SUBROGATION.

**SURFACE** (OF., Fr. *surface*, from Lat. *superficies*, upper side, surface, from *super*, above + *facies*, form, figure, face). The boundary between two portions of space. As a point in a plane is determined in general by two intersecting lines, so a point in space is in general determined by three intersecting surfaces. These surfaces may be plane, quadric, or of higher order according as their equations are of the first, second, or higher degree in the linear coördinates of the system. Thus in Cartesian coördinates (see COÖRDINATES) the general equation of the first degree in  $x, y, z$ , or  $ax + by + cz + d = 0$ , is represented by a plane. The general equation of the second degree in  $x, y, z$ , or  $ax^2 + by^2 + cz^2 + 2fyz + 2gzx + 2hxy + 2kx + 2my + 2nz + d = 0$ , is represented by a conicoid, or surface of the second order, also called a quadric surface. By a suitable transformation of coördinates the general equation of the second degree may be transformed into one or the other of the forms (1)  $Ax^2 + By^2 + Cz^2 = D$  or (2)  $Ax^2 + By^2 = Cz$ . Surfaces having the symmetric equation (1) are symmetric with respect to the origin as a centre and are called central quadrics. Noncentral quadrics are included in equation (2). If  $A = B = C$ , equation (1) takes the form  $x^2 + y^2 + z^2 = K$  ( $= r^2$ ), the equation of the sphere (q.v.). The general equation (1) represents either an ellipsoid (q.v.) or an hyperboloid. If  $D = 0$ , and  $A, B, C$  are not all positive, equation (1) represents a conical surface whose vertex is at the origin. Equation (2) is represented by the surface of a paraboloid (q.v.).

A surface through every point of which a straight line may be drawn so as to lie entirely in the surface is called a ruled surface. Any

one of these lines which lies on the surface is called a generating line of the surface. The cylinder, cone, hyperboloid of one sheet, conoid (q.v.), and the hyperbolic paraboloid (see PARABOLOID) are ruled surfaces. There are two distinct classes of ruled surfaces, those on which the consecutive generators intersect and those on which they do not. The former are called developable and the latter skew surfaces.

If the degree of the equation  $f(x, y, z) = 0$  is higher than the second, the surface representing it will be of an order higher than the second. In discussing the properties of such surfaces, especially the nature of the surface in the vicinity of any given point, the equation of the tangent plane at that point is necessary. This plane is the locus of all tangent lines through the given point, and will meet the surface of the  $n$ th order in a curve of the  $n$ th degree, since each straight line meets this curve in  $n$  points. The point of contact of the plane with the surface will be a singular point on the curve. (See CURVE.) The section of any surface by a plane parallel and indefinitely near to the tangent plane at any point is a conic and is called the indicatrix at the point. Thus points of a surface are called elliptic, parabolic, or hyperbolic, according as the indicatrix is an ellipse, parabola, or hyperbola. If every straight line through a point ( $x', y', z'$ ) of a surface meets the surface in two coincident points, the point ( $x', y', z'$ ) is called a singular point. If the tangent lines at any point form a cone the point is called a conical point; if they form two planes the point is called a nodal point. Similar to the envelope of a family of curves, the envelope of a family of surfaces is the locus of the ultimate intersections of a series of surfaces produced by varying one or more parameters (q.v.) of an equation. The curve in which any surface is met by the consecutive surface is called the characteristic of the envelope. Every characteristic will meet the next in one or more points, and the locus of these is called the edge of regression or cuspidal edge of the envelope. The conditions for convexity and concavity, different orders of contact, and various other properties are best obtained from works on analytic geometry.

**SURFACE, JOSEPH.** A sentimental, plausible hypocrite in Sheridan's *School for Scandal*.

**SURFACE TENSION.** The property by virtue of which the surface of a liquid tends to contract to a minimum area. It is measured in ergs per square centimeter. See ABSORPTION; CAPILLARITY.

**SURF BIRD.** A remarkable plover-like bird

(*Aphriza virgata*) widely distributed on the coasts and islands of the Pacific Ocean, and common along the entire west coast of North America. It is about 9½ inches long, dark ashy brown above, white beneath, everywhere more or less spotted, streaked, or barred with black. The feet are like those of a sandpiper, but the bill is plover-like, short and thick. The wings are very long and acute, reaching beyond the end of the tail when folded. It is clearly related to the turnstone (q.v.).

**SURFBOAT.** See LIFEBOAT; LIFE-SAVING SERVICE.

**SURF DUCK,** or SURF SCOTER. See SCOTER.

**SURF FISH.** A fish of the suborder Halaconoti and family Embiotocidae, related to the percoids. Many species occur on the Pacific

A SURF FISH, THE ALFIONA.

coast of the United States, where they inhabit bays and the surf on sandy beaches. They are small, oval-oblong, compressed, and often very handsome, with stripes, spots, and effusions of various colors. Their flesh is not very highly regarded. The fact of greatest interest connected with them is that they are viviparous. One of the largest and most useful of the family is the "alfiona" (*Rhacochilus toxotes*).

**SURF SMELT.** A small, firm-fleshed, and fat smelt (*Hypomesus pretiosus*) of the coast of California and northward, valued as food. It spawns in the surf, and is netted in great quantities. See Plate of WHITEFISH, SMELTS, ETC.

**SURGEON, CONTRACT.** See CONTRACT SURGEON.

**SURGEON, MILITARY AND NAVAL.** The titles of assistant surgeon, surgeon, deputy surgeon-general, and assistant surgeon-general, once used to designate officers in the medical department of the United States army, were discontinued under the Act of 1908, and the titles for all medical officers, except the surgeon-general of the army, became the military rank followed by the words Medical Corps, e.g., captain, Medical Corps. The title surgeon, however, was retained to designate the duty to which assigned, e.g., the senior medical officer of a territorial department of a tactical division is known simply as the department or division surgeon. In the Dental Corps, also, the terms dental surgeon and acting dental surgeon were retained. A civilian physician, temporarily employed, is known as a contract surgeon. Officers in the Medical Corps of the United States army are first commissioned as first lieutenants; after three years' service they automatically become captains after examination. No person can receive an appointment unless he shall have been examined and approved by an Army Medical Board. The applicant must be between 22 and 30 years of age, must be a citizen of the United States, must have a satisfactory general education, must be a graduate of a reputable medical school legally au-

thorized to confer the degree of doctor of medicine, and must have had at least one year's hospital training, including practical experience in the practice of medicine, surgery, and obstetrics, or the equivalent of this practice after graduation.

**Medical Reserve Corps.** This was established by Act of Congress dated April 23, 1908, for the purpose of securing a reserve corps of medical officers, available for military service. They rank as first lieutenants and are appointed by the President, from graduates of reputable schools of medicine, after a prescribed examination. They must be between 22 and 45 years of age. They receive pay only when called into active service, which is voluntary, but in case of failure to respond their commissions are forfeited. They are not entitled to retirement or promotion. From this corps are obtained the large majority of regular medical officers under the provisions of the Act of 1908.

The titles of most of the medical officers of the navy still include the word "surgeon." The titles, with rank, are as follows: surgeon-general (rank of rear admiral); medical director (rank of captain); medical inspector (rank of commander); surgeon (rank of lieutenant commander); passed assistant surgeon (rank of lieutenant); assistant surgeon (rank of lieutenant, junior grade); acting assistant surgeon (Medical Reserve Corps), dental surgeon, acting assistant dental surgeon, and assistant dental surgeons all have the rank of lieutenant, junior grade.

The Royal Army Medical Corps of Great Britain is a distinct branch of the service, under its own headquarters organization. Members of the corps are trained for military as well as medical emergencies. The Sanitary Troops of Germany and France are organized on similar lines to the United States, differing in details due to general army organization. See **ARMY ORGANIZATION**; **HOSPITAL CORPS** and section *Army*, under the different countries; **MEDICAL DEPARTMENT, U.S.A.**; **MEDICAL DEPARTMENT, U.S.N.**; **SURGERY, MILITARY.**

**SURGEON FISH** (so called from the lancet-shaped spine), or **SEA SURGEON**. One of a family (Teuthididae) of tropical Oriental fishes, of which about 80 species are recognized, and which feed upon seaweeds. Those best known are of

SURGEON FISH.

a, position of the lancet and its sheath.

the genus *Teuthis*, called "barberos," "lancet fishes," "tangs," and so on, and characterized by the possession of a long, sharp, lancet-like spine on each side of the caudal peduncle. The spine is movable and shuts into a groove along the side of the tail.

**SURGERY** (Fr. *chirurgie*, surgery, from Fr. *chirurgien*, surgeon, from Lat. *chirurgus*, from Gk. χειρουργός, *cheiourgós*, surgeon, handicraftsman, from *χείρ*, *cheir*, hand + *ἔργον*, *ergon*, work). The treatment of disease and the correction of deformity or defect by manual and operative procedures, with or without the use of drugs. This branch of medical science is subdivided: (1) According to the nature of the procedure employed, into general surgery, which deals with all manner of cases; orthopedic surgery, which pertains to the correction of deformity; plastic surgery, which involves the building up of tissues and the restoration of lost parts, principally by the transfer of tissue. (2) According to the region involved, into intracranial or brain surgery; ophthalmic or eye surgery; aural or ear surgery; abdominal or visceral surgery, et cetera. Many factors have contributed to the development of surgery. Among these may be mentioned the gradual accumulation of knowledge concerning anatomy and physiology; the discovery of the circulation of the blood; the perfection of the microscope; and the attainment of skill in the invention and manufacture of instruments and apparatus. The discovery of anesthesia and antiseptics, by eliminating much of the pain and danger for the patient, and by lessening the difficulties and inconveniences for the surgeon, has broadened the scope of surgery so that many patients who formerly would have been treated solely with plasters and potions are now subjected to surgical intervention. Surgery, therefore, as practiced to-day, is the product of evolution to which all the ages have contributed.

#### HISTORY

**Ancient.** The surgery of antiquity, although limited in scope and crude in practice, foreshadowed much that is familiar to-day. The lack of knowledge of anatomy, physiology, and other departments of medical science, and the inferior equipment in point of instruments and apparatus, did not deter the ancients from the performance of many daring feats of surgery. The ancient Egyptians (as related in the *Papyrus Ebers*, 1552 B.C., and in other records) are said to have performed with success and dexterity many operations, notably, castration, lithotomy (removal of calculi), amputations, and various operations upon the eye. The Hindus, like the Egyptians, were familiar with surgical practices, such as the treatment of fractures, the removal of calculi, etc. Indeed, the ancient Hindus are credited with having originated plastic surgery thousands of years ago. It is recorded that a certain Hindu ruler imposed upon the inhabitants of a conquered city the punishment of cutting off the nose, none escaping save infants and players upon wind instruments. The prevalence of this disfigurement called forth efforts upon the part of the inhabitants to repair the defects thus caused. The tile makers, a more or less despised class, were the first to meet with success in this art. Presumably these artisans were inspired to undertake such work because of their familiarity with cements and different processes of repair calling for adhesion.

The surgery of the early Greeks seems to have been largely that of the battlefield and, like medicine, to have been derived from the ancient Egyptians. It was purely empirical

and was practiced largely by the priesthood or by head shavers and embalmers delegated by the priests, who were themselves averse to the shedding of blood. This sacerdotal or guild medicine and surgery prevailed until the time of Hippocrates (q.v.). The studies, practice, and writings of Hippocrates embraced surgery as well as medicine, though he gave to the world no landmark in surgical procedure. The ancient Romans contributed little to either medical or surgical science. According to Pliny, they believed the dignity of the Roman did not permit him to make a profession of medicine, which they were accustomed to associate with the bleeders, head shavers, and similar representatives of the sacerdotal medicine and surgery of the Greeks. Little definite progress, indeed, marked the evolution of surgery until the rise of the Alexandrian school. During this period (233-30 B.C.) surgery was placed upon a basis of diagnostic precision and operative daring as a consequence of the study of human anatomy. For the first time in the history of the world superstition was overcome to such an extent that Herophilus, the founder of the study of human anatomy, and others of this school, dissected the human body without interference.

**Mediæval.** Mediæval surgery embraced the long period which elapsed from the decadence of the Alexandrian school to the beginning of the sixteenth century. Three men are said to have brought the whole surgery of the ancient world to a focus in their writings during this time. Cornelius Celsus (25 B.C.-50 A.D.), Claudius Galen (131-201 or 210 A.D.), and Paulus of Ægina (c.625-690 A.D.), virtually shaped the destiny of surgery throughout the Middle Ages. Byzantine and Arabian medicine helped to foster surgery, and during the latter part of this period European countries, with Italy in the forefront, began to make their impress upon medical and surgical thought, adding many illustrious names to the list of distinguished surgeons. It was during this period that a distinct separation of medicine and surgery began to be noted. The priests and monks, who were likewise the physicians, being averse to the shedding of blood, shrank from the surgical treatment of their charges. Growing out of this attitude, which was brought over from ancient to mediæval times, and likewise in response to the customs imposed upon the priesthood of shaving the head and of being bled at regular intervals, there developed the craft known as barber surgeons. The first duty of these individuals was the shaving and bleeding of the priests and monks; they also assumed the task of administering surgical treatment to all who asked. In France, however, about the middle of the thirteenth century, a new order of surgeons arose—ambitious young men who sought to dignify their calling. Members of this new fraternity were known as surgeons of the long robe, in contradistinction to the barber surgeons, who were known as surgeons of the short robe. Great rivalry, quite naturally, marked the history of these two orders of surgeons. The guild of surgeon barbers underwent gradual evolution, becoming in time the corporation of barber surgeons, composed of representatives of the orders of both the long robe and the short robe. Not only did this organization flourish in point of numbers, but its members were accorded military prestige and court favor throughout Europe.

Thus, in England, in 1461, Edward IV granted a charter to the Corporation of Barber Surgeons, and the charter of the surgeons of London was confirmed by Henry VIII.

**Reconstruction.** The reconstruction period of surgery, embracing the sixteenth, seventeenth, and eighteenth centuries, received the benefit of many important discoveries bearing directly upon surgical practice which were made before surgery was thoroughly emancipated from the stigma of its humble origin, and from the ignorance, superstition, prejudice, and intolerance which hindered progress in all directions during the Middle Ages. Much of the credit of the final emancipation belongs to Ambroise Paré (1510-90), often called the father of modern surgery, who was a member of the Corporation of Barber Surgeons. He was apprenticed to a barber surgeon when, as a youth, he went to Paris. He soon entered the great hospital, the Hôtel Dieu, already the Mecca for ambitious physicians, and was there afforded abundant opportunity for the development of the ability and originality which reflected so much credit upon his guild. When Paré successfully employed the method of ligating arteries in order to control hemorrhage, thus eliminating the old method of searing the bleeding part with the red-hot iron (the actual cautery), he literally inaugurated a new era in surgical practice, of which the control of bleeding is a prime requisite.

It was during this reconstruction period that William Harvey (1578-1657) discovered the circulation of the blood, thus placing anatomy, physiology, and surgery on a different and more secure basis. Antony van Leeuwenhoek, the Dutch lens maker and naturalist (1632-1723), still further revolutionized scientific investigation by making a lens powerful enough to reveal the hitherto unseen forms of life and the minute structure of matter. His contribution to the evolution of the microscope (q.v.) made possible the discovery by Sir Robert Hooke (1635-1703) of the cellular structure of plants, and by Marcello Malpighi (1628-94) of the cellular composition of the blood and of other details of minute structure, thus paving the way for the brilliant investigators of the nineteenth century, who still further revolutionized surgical practice by discoveries in bacteriology, pathology, etc.

The latter part of the reconstruction period of surgery was particularly prolific of men whose achievements tended finally and firmly to place surgery on a plane equal in all respects with that occupied by medicine—France and England being unquestionably in the lead. To Peyronie (1678-1747), of Montpellier, is given the credit for having finally effected the separation of the surgeons from the barbers in France, and for wielding a powerful influence in furthering the welfare of his profession in general. Petit, Brador, Desault, and a host of others contributed to the advancement of surgery in France during the latter part of this period. In England the names of such men as William Cheselden, Alexander Munro, Sir Percival Pott, William and John Hunter, and many other familiar names, appear upon the honor roll of this brilliant era. In Germany, Heister; in Austria, Mohrenheim; in Italy, Scarpa; in Spain, Gimbernat—all were among the distinguished representatives of surgery in their respective countries. In America, during this

period, especially during the latter part, a number of surgeons left their impress upon coming generations of surgeons, chiefly as teachers in different medical schools.

**Modern.** The era of modern surgery may be said to begin with the nineteenth century—a century of epoch-making surgical discoveries and accomplishments. The surgeons of the beginning of this century were hampered, it is true, by a total lack of knowledge concerning many essentials which are matters of common information and practice to-day. They knew little more than their mediæval and ancient predecessors concerning the causes of danger from surgical operations. The true significance of surgical shock was unknown to them, and post-operative sepsis was an enigma. They lacked many of the instruments of precision, such as the fever thermometer and the hypodermic syringe, now familiar to every layman. Yet it has been said, and doubtless truthfully, that more progress has been made in surgery since the year 1800 than in twenty centuries preceding that date.

The first epoch-making event of the nineteenth century was the performance of ovariectomy in the treatment of ovarian disease, this surgical feat having been accomplished by Ephraim McDowell, of Kentucky, in 1809. While it is recorded that jealous males many centuries before were wont to subject the females of their ménage to castration, and while ovariectomy had been accidentally or incidentally performed by surgeons of the eighteenth century (Houston, of Glasgow, in 1701, and Laumonier, of Rouen, in 1781), McDowell was the first intentionally to perform the operation for the specific purpose of curing disease of this organ. When this feat of surgical practice became known and credited, the abdominal cavity was no longer *terra incognita*, to be explored only in cases of dire necessity. It then became the field of observation by the skillful surgeons who in different countries emblazoned their names upon the surgical Hall of Fame in the preanæsthetic period of modern surgery. Nathan Smith, of Massachusetts, who performed ovariectomy in 1821, without knowing of McDowell's work; Valentine Mott, of New York, who ligated important blood vessels in the treatment of aneurysm, among many other achievements; J. Marion Sims, of Alabama and New York, who is called the founder of modern gynecology; Samuel D. Gross, of Philadelphia, a great surgeon and a great teacher; and a long list of others might be mentioned among forceful surgeons. In Great Britain, Sir Astley Cooper, Sir Charles Bell, James Syme, and a brilliant coterie of surgeons were making their impress upon the surgical world during this prolific period. In France, Germany, and Italy—in fact throughout the civilized world—the seed was being sown for the abundant harvest of surgical endeavor which followed the introduction of anæsthesia.

The discovery of anæsthesia (1842-47) (q.v.) and the perfection of the various methods of rendering one insensible to pain conferred a blessing upon humanity which is not confined to the patients alone, but which is shared by the surgeon and all concerned in the performance of surgical operations. Major surgery and much of what we now call minor surgery were practically impossible in the preanæsthetic days, as the patients could not endure the pain

and neither the surgeon nor his attendants could stand the strain of prolonged and difficult operative procedures. With the discovery of anæsthesia the barrier to progress was removed so far as the possibility of the actual operation was concerned. There still remained, however, the old-time bugbear—hospital gangrene, septicæmia, pyæmia, tetanus—one or more of which could always be reckoned with to nullify, to a greater or less degree, the surgeon's work. It was not until Pasteur (1822-1895) (q.v.), the French physician-chemist, evolved his germ theory and gave to the world his discovery that fermentation is caused by microorganisms, that surgery was finally and fully developed into what has been called "the seeing portion of the healing art."

When Sir Joseph Lister, in 1867-68, applied the discoveries of Pasteur to surgery, and formulated his theory concerning sepsis and antiseptics, the last obstacle to progress was removed. With the pain and inconvenience of the actual surgical procedure nullified, and with the danger of post-operative infection reduced to a minimum, surgery entered upon a new era of triumphs, the period of modern surgical science. Every part of the body has been brought within the domain of this new surgery. Not a tissue, not an organ, not a cavity of the body is now exempt. Surgical practice has undergone many changes, in general, as well as in specific details. Specialism has developed to a pronounced degree, until the field of general surgery is now subdivided into regional surgery, surgery of the brain, the eye, the ear, the chest, the abdomen, and other special regions. A further specialism concerns itself less with regions of the body than with diseases, a notable example of which is cancer.

Perfection of technic has been very greatly facilitated of late years by the more rational attitude of the public in general and of law-makers in particular with reference to securing material for the dissecting room, the autopsy, and the surgical laboratory. Happily, enlightened sentiment no longer makes body snatching a necessity, nor does it permit of such demonstrations against the dissection of the human body as the Doctors' Mob of 1788, which raged for two days in New York, despite the efforts of civil and military authorities to quell it. State control of the disposition of the bodies of certain classes of persons dying unclaimed has contributed largely to the improvement of medical education, in consequence of which surgery, along with medicine, has received a decided impetus.

The surgery of the twentieth century, as may be seen from the foregoing brief historical review, is the product of evolution, the factors involved being many and diverse, some very old, and some hardly older than the century.

#### SCOPE

**Purposes.** The purposes of surgery have been modified and its domain greatly extended as the result of the epoch-making discoveries chronicled above. Surgery is now resorted to for purposes of: (1) diagnosis (exploratory laparotomy; intracranial exploration or exploratory craniotomy; excision, under certain circumstances, of tumor or other tissue for microscopic examination, etc.). (2) The correction of deformity or defect. (3) The cure of disease.

(4) The amelioration of suffering. (5) The prolongation of life.

**Diagnostic.** In diagnosis surgery is frequently called into requisition. With the general progress in medicine and surgery which has marked the last quarter century, modern methods of diagnosis—chemical, bacteriological, physical, and electrical—have brought us into intimate acquaintance with body cavities which were formerly but rarely explored and but little understood. This is particularly true of the abdominal cavity. The surgeon, by means of the various methods mentioned, is enabled to predict, with a fair degree of accuracy, what will be revealed by operation. In many cases, however, it is impossible, by any external diagnostic methods, to ascertain the exact conditions to be dealt with, and to determine the remedial measures to be employed. In such cases exploratory operation is indicated, not always as a last resort, but often as an early means of making an absolutely correct diagnosis. This is particularly true with reference to the abdomen. The most telling arguments in favor of opening the abdomen and seeing and feeling the actual condition are cases of cancer of the abdominal or pelvic organs, in which patients have been allowed to go untreated, or to be incorrectly treated (in consequence of mistaken diagnosis), until it is too late for curative surgical intervention. It is sometimes necessary, likewise, to resort to exploratory craniotomy in cases of obscure brain lesions, it being impossible, in some instances, to make an absolute diagnosis of abscess or tumor of the brain by other means. In the case of an external tumor, as of the breast, particularly in the early stage of development, it is impossible to determine positively whether such tumor is of benign or malignant (cancerous) nature until a section is removed and studied under the microscope. The microscopical examination in such cases should be made at the time, in order that, if the growth is found to be malignant, it may be immediately extirpated, thus obviating the danger of disseminating cancer cells.

**Corrective.** In the correction of deformity the orthopedic surgeon has a very wide and beneficent field of usefulness. Orthopedic operations were undertaken centuries ago, but, like all other branches of surgery, its greatest achievements belong to the period since the discovery of anæsthesia. Clubfeet, bowlegs, curved and otherwise deformed spines, congenitally dislocated hip joints, harelips, cleft palates, and many other deformities, which years ago were allowed to go uncorrected, now receive attention during the formative period of life, when nature has ample opportunity to finish the work of correction begun by the surgeon. Many persons thus reach adult life with so little evidence of their early deformity that they may be considered normal adults in every sense of the term.

In the correction of defects which are the result of accident or disease (in contradistinction to the deformities which are of congenital origin, or born with the individual) plastic surgery is called into requisition. This branch of surgery, too, as we have already seen, is not new, though it has been markedly extended and amplified since the modern era was inaugurated. Some surgeons, not content with employing plastic methods in the repair of defects

caused by accident, have entered the field of cosmetic surgery, the purpose of which is to improve upon the work of nature in response to the vanity of the subject. There are cases, however, in which such deformities as crumpled ears, markedly humped or saddleback noses, and other conditions through which the individual suffers inconvenience and embarrassment, are sufficient to warrant recourse to plastic surgery. The most important work in this field, however, consists in the correction of defects which result from accident or disease. Sometimes, following injury or burns, scar tissue forms to such an extent as to cause deformity and to interfere with the use of the organ or part involved. By dissecting out the cicatricial tissue and filling in the defect with a flap from some other portion of the patient's body, the contour of the disfigured part may be greatly improved and its usefulness restored. Sometimes tumors are so situated that their complete removal leaves a marring defect. By means of autoplasmic or heteroplasmic skin grafts or flaps this may be so completely overcome that no evidence of the defect remains. Lupus (tuberculosis of the skin), cancer, and other diseases may cause such deformity as to necessitate, or at least to render advisable, the utilization of plastic surgery. In advanced cancer, when it is no longer possible thoroughly to eradicate the disease, it is possible to remove all superficial evidence and then resort to palliative repair, thus possibly keeping the disease confined, at least for a time, to the deeper structures. For example, cancer may involve the nose, extending into the bones of the cheek and jaw, so that the removal of all macroscopical evidence of the disease would entail the removal of practically the entire half of the face. It is possible, in such instances, to remove all superficial manifestation of the disease and to fill in the defect by plastic flaps, leaving the patient far more comfortable and more presentable for the remainder of life than would have been the case without the plastic intervention. Such patients may live for months with irremovable cancer, all the while oblivious to the fact that they have not been entirely cured of this affection, and may die from some disease in no way associated with the cancer. There is, perhaps, no phase of plastic surgery more beneficent than that which deals with the plastic and palliative repair in cases of malignant disease.

**Curative.** In the cure of disease surgery is employed in such a diversity of ways and for so many conditions that every part of the body, literally "from the crown of the head to the tip of the toe," is amenable to treatment by operative measures.

As the osseous system of the bony framework of the body has long been the subject of surgical experimentation in the correction of deformities and abnormalities, so also has it received attention in the cure of diseases involving its integrity. Thus, in the treatment of sarcoma, tuberculosis, osteomyelitis, and of bone affections, great progress has been made. Sir Arbuthnot Lane of London, who originated the valuable procedure known as bone plating; Dr. John B. Murphy of Chicago, who has contributed excellent work to the technic of arthroplasty, or the plastic surgery of the joints; Dr. Fred A. Albee of New York, who has contributed to the surgery of the spine by his

work on bone transplantation and osteoplasty in the treatment of certain affections of the spine; and many others working along similar lines have blazed new trails or shed new light upon paths previously explored.

The brain, which in former times it was considered a sin to "cause to sleep," is now with impunity not only rendered inactive for the time by anesthetics, but is subjected to inspection and operation just as any other part of the body. Tumors are removed, abscesses evacuated, blood clots and other obstructions to the vessels cleared, and many other operations performed upon all parts of the brain. The spinal cord, too, is subjected to surgical treatment. It is also utilized for purposes of spinal analgesia, the patient being rendered insensible to operations in certain localities of the body without being rendered unconscious. This is accomplished by injecting into the spinal canal given quantities of certain analgesic agents, such as cocaine, novocain, and stovaine. The peripheral nervous system, like the brain and spinal cord, is amenable to surgical treatment in the relief of affections of the nerves themselves or in the course of the surgical care of other diseases. In severe neuralgias, such as facial and supra-orbital neuralgia, injections of alcohol or other substances into or near the nerves involved will sometimes give relief. Cutting nerves and dissecting out parts of the nerves or the ganglia from which they arise will likewise relieve intractable cases of neuralgia. In some cases of advanced cancer, when little more can be done surgically, great relief can be given by cutting nerves pressed upon by the malignant growth.

The vascular system, including the heart, has been brought within the domain of experimental and practical surgery, with the result that many cases which in former years would have been considered impossible of surgical treatment are now promptly subjected to such measures. A large amount of interesting and valuable experimental work upon animals has been conducted by Dr. B. Merrill Ricketts of Cincinnati, Dr. Alexis Carrel of the Rockefeller Institute, New York City, and others, all looking to the application of principles and technic to the surgery of the human vascular system. A large proportion of the practical surgical work upon the heart deals with injuries to this organ, the majority of these being stab or gunshot wounds. It is estimated that from 25 to 35 per cent of patients subjected to operation recover. A larger percentage of cases of milder severity result in recovery after operation. Contusions and ruptures of the blood vessels, and wounds made by sharp weapons or bullets, are treated by ligation, removal of clots, or other accumulations of blood (hæmatomas) and ligation of both ends of the vessel or repair by anastomosis. Clots or thrombi and emboli (composed of air cells, bacteria, or fat), causing obstruction of the vessel involved, require surgical removal. Aneurysm (q.v.) has been given a great deal of attention with regard to treatment by surgical means, many operations having been devised. The ligation of arteries for the control of hemorrhage has played an important part in surgical practice since Ambroise Paré introduced it in the sixteenth century. With the discovery of the circulation and the development of knowledge concerning the part played by the blood in the nourishment of normal, as well as abnormal, tissue the method

of ligating arteries increased in scope. It then came to be applied, not only for the control of hemorrhage occurring as the result of accident or surgical procedure and for the treatment of aneurysm, but for the purpose of causing atrophy or shrinkage of organs or other parts of the body under certain circumstances and to lessen the nutrition of inoperable or irremovable new growths, thus checking further development and perhaps causing disappearance. The last-named use of the ligature has given rise to the term "starvation ligature." The procedure has been applied to the uterus, ovaries, testes, spleen, thyroid gland, tongue, and other organs. The method has been found particularly useful as employed by the late Dr. R. H. M. Dawbarn of New York City in the treatment of irremovable tumors of the head and face and by Dr. William Seaman Bainbridge of New York City in the treatment of advanced cancer of the pelvic organs.

The respiratory system, like the nervous and vascular systems, has been a prolific field for surgical investigation. The history of the surgery of this particular part of the body has been entirely rewritten within the last few years in consequence of the researches of Sauerbruch, Willy Meyer, Meltzer, Elsberg, Ricketts, and others who have devised means of operating upon the lungs and other thoracic viscera without collapse of the lungs. This is accomplished by various kinds of apparatus, all designed for maintenance, during operation, of the necessary differential air pressure, i.e., the maintenance of the normal intrapleural negative pressure, or compensating for this by increasing the pressure of the inspired air. The two methods are called the hypotatmospheric and the hyperatmospheric methods. The Sauerbruch pneumatic cabinet, which was the first successful apparatus for this, belongs to the former class, maintaining a negative pressure of about eight millimeters of mercury. The Meyer universal differential cabinet provides for increase or decrease of pressure. Meltzer's intratracheal insufflation method provides for intrapulmonary positive pressure and is relatively simple. By employing one of the numerous methods for securing the required differential air pressure it is possible to treat injuries or diseases of the lungs and pleura by surgical means.

The scope of the surgery of the gastrointestinal tract has been markedly widened since the introduction of anesthesia and antisepsis. Conditions which a few years ago were considered amenable only to rest, diet, and medication are now subjected to surgical treatment. Ulcers and tumors are excised from any portion of the gastrointestinal tract. Injuries are repaired, adhesions resulting from inflammatory processes broken up, portions of the tract which are angulated or otherwise distorted as a result of adhesions are made free and restored to normal function. Under certain circumstances it is considered justifiable and feasible to remove portions of the stomach and intestine, as for ulcer or cancer. Not infrequently a malignant involvement of the intestine is so extensive as to necessitate the removal of several feet of gut. In such event the severed ends are disposed of by end-to-end anastomosis or by tying off one end and uniting the other, by end-to-side anastomosis, with another portion of intestine. Especial attention has been directed to the surgery of the intestine of late years in connection

with a condition to which Sir W. Arbuthnot Lane of London has applied the term "chronic intestinal stasis."

The biliary system (liver, gall bladder, and appendages) has called forth considerable consideration, and more radical procedures are now employed than were thought possible. An example of this may be noted in the tendency to remove the gall bladder, in the presence of gallstones, rather than to remove the stones and drain. Prof. Hans Kehr of Berlin, among others, has long practiced cholecystectomy, except in cases with small stones and in certain other conditions. Many surgeons advocate this procedure as a prophylactic measure with regard to cancer of these organs.

The genitourinary system (kidneys, bladder, and organs of reproduction) involves a very large number of operative procedures. The surgery of the female generative organs (uterus, ovaries, Fallopian tubes, etc.) is a field in which wonderful achievements have been recorded. The present trend in the surgical treatment of these organs is towards conservatism. The tendency to sacrifice all ovarian and uterine tissue, unless actually diseased, is much less marked than a few years ago. This attitude is in part the result of what has been learned of late years concerning the influence of these organs upon development, health, and the maintenance of general mental and physical equilibrium.

A comparatively new and very important phase of surgery is concerned with the treatment of conditions resulting from disordered function of the ductless glands and other organs having an internal secretion (endocrinous glands). The pineal and pituitary glands (in the brain), the thyroid, parathyroids, and thymus glands (in the neck), the pancreas, the suprarenal bodies, the liver, the spleen, the sexual glands (ovaries and testes), and other structures are now classed among the organs of internal secretion. The functions of these, as regards internal secretions (hormones), are supposed to be so interrelated that complete differentiation is impossible. The thyroid, however, has been called "the monitor" of the entire endocrinous system and seems to be concerned so generally and extensively with the physiological as well as the pathological processes of the body that surgical attention has been directed towards it very widely of late. Theodor Kocher of Bern, one of the leaders of the surgical profession, is well known through his operations on the thyroid gland.

**Ameliorative.** In the amelioration of suffering surgery is often employed where it is no longer hoped to effect a cure. Palliative methods are employed more extensively in the relief of cancer than of any other disease. The limit of operability of this malady has been greatly extended by modern methods. When it is not possible to remove all the disease and to effect, by its removal, a cure, suffering may be relieved and the patient rendered otherwise more comfortable by the cutting of nerves that are pressed upon by the tumor masses, by the removal of such portions of the malignant growth as impinge upon other organs, causing pain or impaired function, and by clearing up ulcerating areas and skin grafting. Sometimes very large areas of degeneration may be cleared up, especially with the aid of certain forms of electricity (fulguration, after the method of

De Keating-Hart), and the surface covered with grafts from other portions of the patient's body, from other persons, in rare instances from the dead, and with egg membrane or other tissues. No matter how short the remaining span of life, whether weeks, months, or years, the chances are that the patients with irremovable cancer may be rendered more comfortable by these palliative operations.

**Prolongation of Life.** In the prolongation of life, aside from that which comes with the cure of disease, surgery may often be successfully employed. A specific illustration of this may be found in the method of ligating arteries which supply malignant neoplasms of certain regions, notably the face and neck, supplied by the carotid arteries, and the pelvic organs (uterus and ovaries). Obstructions in the air passages and in the gastrointestinal tract which are of sufficient degree to endanger life or to render life all but unbearable may be sufficiently relieved by surgical intervention, and may enable the individual to continue life for a time in a fair degree of comfort.

#### METHODS

**Equipment.** Surgical equipment has undergone an interesting metamorphosis with the general dissemination of knowledge, with the development of mechanical skill, and with the evolution of surgical science. This applies to instruments, apparatus, hospital and operating-room construction and equipment, and to all the paraphernalia concerned in the operative treatment of disease. The refinements of technic have made necessary the most skillfully constructed instruments, light, durable, and capable of thorough sterilization. A uniform requirement of modern surgical instruments is that they be so constructed and of such material as to permit of sterilization in all parts. For this purpose simplicity of mechanism is to be desired. Metals capable of withstanding the necessary degrees of heat and the action of antiseptic fluids are employed in all surgical instruments. The evolution of the operating table has kept pace with that of instruments. Instead of wood, sometimes combined with leather or heavy fabrics, as of old, the operating table to-day is made entirely of metal or metal combined with glass. All pads and pillows are detachable, and covered with sterile linen when in use. A properly constructed table may be kept thoroughly clean and polished in all its parts. Pans and other vessels employed in connection with the operation are of enameled ware or material not affected by heat and antiseptic fluids. The surgeon of to-day, fully comprehending the significance of sepsis and antisepsis, operates, whenever possible, in the most up-to-date operating room or surgical amphitheatre. If, however, the proper precautions are observed, particularly with regard to the immediate field of operation, entirely successful surgical work may be done in private houses, with improvised facilities.

The properly appointed hospital operating room contains as little wood as possible, no draperies, carpets, or other dust and germ holding appurtenances. Walls, floors, and furniture must be capable of washing by whatever method may be desired in the individual case. Various methods have been devised for flushing out operating rooms after each operation. Many

of the most modern hospitals have eliminated all corners and sharp turns in the effort to facilitate cleanliness. Ample facilities for sterilization of hands, instruments, dressings, etc., are provided. The surgeons and all operating-room attendants who come in contact with the patient and the sterilized operating-room appointments are provided with sterile caps and gowns, and in some operations the surgeons, as well as the patient, are given the further protection of the sterile masks and rubber gloves worn by the operators.

**Technic.** Preparation for operation concerns the operating room and all its appurtenances, the surgeon and attendants, and the patient, and varies with the nature and severity of the surgical intervention. In emergency surgery it is often impossible to wait for the preliminary precaution otherwise adopted. In such cases the rules of asepsis must be conformed to as nearly as possible according to the urgency and severity of the condition demanding surgical treatment. Under all ordinary circumstances, however, the operating room and surgical equipment are ordered to suit the requirements of the individual case, and all instruments, dressings, gloves, caps, gowns, etc., are sterilized and ready for use before the operation is begun. The methods of sterilization vary according to the preference of the surgeon. As a rule, however, instruments are sterilized by boiling for 15 minutes in a 1 per cent solution of sodium bicarbonate. The trays upon which the instruments are conveyed to the operating table as they are needed are thoroughly washed in a 0.2 per cent solution of bichloride of mercury and then lined with sterile towels. All the basins and other vessels employed during the operation are sterilized by washing in a 0.2 per cent solution of bichloride of mercury. All dressings, towels, sheets, caps, gowns, and masks are sterilized by exposure to steam at 250° F. for one hour, especially constructed apparatus being devised for the purpose. Suture and ligature materials, which are manufactured under careful supervision and placed upon the market in sterile form, are subjected to further sterilization immediately before being used. The hands and forearms of surgeons and attendants are carefully prepared immediately before operation by thorough washing with soap and water, then alcohol (according to the preference of some operators), followed by a 0.1 per cent solution of bichloride of mercury. Some surgeons prefer to do all operative work with sterile rubber gloves; others reserve gloves for septic cases, in which there is danger of infection for the operator.

The preparation of the patient is preliminary and immediate and varies with the nature of the operation and preference of the surgeon. It is generally considered advisable, when an inhalation anæsthetic (ether, chloroform, nitrous oxide, and various combinations and sequences of these with other agents) is to be employed, to begin 24 hours beforehand to clear out the alimentary tract. This prevents nausea and vomiting before and after the operation or renders these disagreeable accompaniments less apt to occur. Twelve hours before operation the skin over the field of operation is prepared by thorough scrubbing, shaving, and covering with a soap poultice. Immediately before operation it is again scrubbed, and sponged off with alcohol and bichloride of mercury solution. It

may be dried thoroughly and painted with tincture of iodine just before operation. Some surgeons use only tincture of iodine on the skin, depending upon two coats painted over the field of operation. Under certain circumstances it is deemed advisable to give preliminary medication to prepare for the anæsthetic. This varies with the needs of the patient, the anæsthetic to be given, and, to some extent, with the preference of the surgeon. The selection of the anæsthetic, likewise, is both a matter of necessity and of preference. For minor operations many surgeons and patients prefer local anæsthesia or analgesia, and some surgeons claim excellent results with major operations performed under this form of anæsthesia. In certain cases, in which local and general anæsthesia are contraindication, spinal analgesia may be employed. By far the larger number of all operative procedures, however, are performed under some method of general or inhalation anæsthesia. A great deal of experimental and clinical work has been carried on with the idea of minimizing the dangers and discomforts which accompany or follow surgical intervention. Dr. George W. Crile of Cleveland has suggested an excellent method of preparing the patient for the anæsthetic and the operation by what he calls "anoci association" which is a combination of suggestive therapy and local and general anæsthesia. Dr. James T. Gwathmey of New York City, by combining the essence of orange with the ether or other inhalation anæsthetic, eliminates or lessens the dread of the anæsthetic so often experienced and the accompanying and postoperative nausea, vomiting, and other disagreeable phenomena. Of late rectal anæsthesia has been employed by a number of surgeons. See ANÆSTHESIA.

The ethics of the operating room safeguard the patient in every way possible. Not only is the patient of the present time given the benefit of the most modern diagnostic methods; of the most careful preparation, on his or her own part as well as that of the surgeon, the attendants, the instruments, and all apparatus employed in the course of the surgical procedure; of the most advanced methods of anæsthesia and antisepsis; of the highest degree of technical skill; and the most careful aftercare, but the law and the higher ethics are both applied in the operating room for the protection of the patient. In some of the United States it is illegal for a surgeon to operate in the presence of laymen not concerned in the execution of the operation, thus protecting sensitive individuals from the gaze of the curious. In all States and in most countries the actual operation must be done by a qualified surgeon or under the immediate supervision of one, who assumes all responsibility in the eyes of the law. It is not permissible in teaching institutions and in well-regulated hospitals for male and female patients to be brought into the operating room at the same time. Undue levity and other manifestations of carelessness or indifference are entirely excluded. The patient and his friends and relatives are thus spared the feeling that there may be any manifestation of disrespect which would be offensive to those unfamiliar with the usual operating-room procedures, and who may therefore be unduly sensitive in such a matter.

With surgery robbed of its terrors by anæsthesia, of its dangers through antisepsis and

skill, and of its discomforts by perfected hospital and operating-room equipment and management, the present is full of achievement and the future of promise in the matter of the surgical treatment of deformity, defect, injury, and disease. See AMPUTATION; HERNIA, and also illustration under BANDAGE.

**SURGERY, COSMETIC.** See COSMETICS.

**SURGERY, MILITARY.** Military surgery is the specialized application of the principles of traumatic surgery, under military conditions, to wounds of war. In its wider connotation it includes the collection and transportation of wounded, the administration and control of mobile and stationary hospitals, hospital trains and ships, and the command of sanitary troops.

Although the ancient history of surgery is legendary, even in the earliest armies there were those who treated the ill and bound the wounds of warriors. The only surgery of the Greeks pictured by Homer (1000 B.C.) was that of the battlefield. As mediæval surgical practice was in the hands of the religious orders until forbidden by the Council of Tours (1163 A.D.) the wounded of armies were left to the care of monasteries. It was only after this proscription that military surgery in Europe began to take form. In the following centuries development in surgical practice arose chiefly from methods applied to wounds in battle. The clinical description of hospital gangrene by Paracelsus, in the early sixteenth century, was based on observations made in military hospitals. In this period Ambroise Paré, as a military surgeon in the campaigns of Francis I in Piedmont, was the first to maintain that gunshot wounds were simply traumatic and not essentially poisoned. In his introduction of the ligature to control hemorrhage, supplanting the cautery iron, he made the first substantial contribution to modern military surgery and made possible the successful performance of major amputations. The tourniquet introduced by Fabriz von Hilden (1560-1634) found its first general application, in an improved form, at the siege of Besançon in 1674. In England in the seventeenth century Richard Wriesman, in the wars of the Commonwealth, first advocated immediate amputation in cases of severe gunshot wound. At that time amputations, treated conservatively, were almost invariably fatal. This practice of amputation continued through the Peninsular, Crimean, and the American Civil War. In 1714 at Berlin and in 1785 at Vienna schools for the teaching of military surgery were founded and have continued to the present day. In the last decade of the eighteenth century, with the approval and encouragement of Napoleon, Baron Larrey introduced mobile field hospitals (*ambulances volantes*) for the treatment of wounds on the battlefield; his colleague, Baron Percy, organized companies of stretcher bearers. The development of the field-ambulance system to its modern form we owe to Surgeon Jonathan Letterman, U.S.A., in the American Civil War.

Coincident with the close of the American Civil War Lord Lister's deductions from Pasteur's discoveries in fermentation, establishing the microbic cause of wound infection, rendered so relatively insignificant all earlier contributions to surgical art and so advanced the methods of wound treatment that the practice of present-day military surgery may be said to date from that time. These principles of antisepsis led to the application of an antiseptic first dressing. Later it was assumed that military wounds in general were sterile, and an aseptic first-aid packet was substituted for the one devised by Von Esmarch containing an antiseptic powder. Now there has been a complete *volte face*. All military wounds are infected. In the milder grades the resistant body fluids may overcome invading microbes and the wound heal without pus formation. Nothing should be left to chance, however, and the first-aid packet, a part of every soldier's personal equipment, should contain antiseptics. The latest form of first-aid packet of the United States soldier contains an ampule of sublimated iodine with which a germicidal solution is to be pre-

pared, in addition to the sterilized pads and bandages for wound dressings

Military surgery, then, is concerned with three cardinal conditions: (a) frequency and forms of battlefield casualties; (b) arms and missiles as related to wounds; (c) care of wounds and the wounded.

Battle losses in killed and wounded are the most important concern of military surgery, as upon the experience of the past must be based the estimates of the future in making provision for the care of the wounded. While losses vary greatly with the character of engagements and

present-day troops will bear with no greater fortitude a larger percentage of losses than soldiers of the past; that after a loss of more than 10 per cent they must be expected to waver, lose their formation, and retreat. Although maximum casualties may attain a greater rate in smaller units in particularly hazardous situations, military estimates are still based on the assumption of 10 per cent battlefield loss.

In the combatant branches casualties have generally been greatest in infantry, less in artillery, least in cavalry. The reports of the

range from inconsiderable numbers to comparative annihilation in occasional disasters, the morale of men in all ages seems to have been so much the same that not only the percentage of losses, but also the ratio of killed to wounded, has remained strangely constant throughout the history of warfare. The losses in the Roman legions which reached 10 per cent were understood to approach so near to disaster that decimation even then attained something of the connotation of annihilation. Analysis of losses in modern battles leads to the conclusion that

Russo-Japanese War, however, show that the losses sustained by Japanese sanitary troops, as officers and men of medical corps are now called, were next in order to those of infantry. In the early stages of the Great War the losses sustained by sanitary troops were relatively greater than those in all other branches, excepting only the field artillery. In the battles of the last 50 years, even with the use of fire-arms of vastly varying degrees of efficiency, and in both the victorious and vanquished forces, an almost constant ratio of one killed to four

wounded has obtained. Such official reports of the Great War as have been made public show a rather remarkable persistence of the ratio of one to four in killed and wounded. While in some of the fiercer engagements of the Western and Gallipoli theatres the killed have even exceeded the wounded, the more mobile actions on the Eastern front have served to maintain the old general average.

The introduction of the military rifle, firing a long small-calibre jacketed bullet at greatly increased velocity, changed the nature of small-arm wounds almost as much as Listerism modified the principles of treatment. The elongation of the old lead ball, for reduction of weight and diminution of air resistance to attain steadiness of flight and to increase range, encountered mechanical limitation in the fouling of the spiral grooving in the rifle with particles of lead stripped from the bullet. The remedy for this was offered by an army surgeon when, in 1875, Surgeon-General Reger of the German army recommended covering a lead core with a jacket of harder metal which would satisfactorily engage the rifling and impart the rotary motion necessary to accuracy of fire. This newly fashioned arm is now known as the small-calibre rifle, and its cylindrical roundheaded bullet is technically termed ogival.

Since 1906 the United States, England, France, Germany, Turkey, and Switzerland have enhanced the efficiency of their small arms by making the point of the bullet sharp, and further increased velocity by reducing air resistance. Prior to the Great War, France and Switzerland again accelerated the velocity of the bullet by tapering its base to about two-thirds the diameter of the waist where it engages the rifling. This change accomplished another reduction of air resistance by applying the principle employed by the naval architect in sharply modeling the stern of a yacht, to allow the displaced medium to press in behind and reduce the back drag. The French bullet now exhibits still another innovation, as it is made solid of brass alloy. These changes may appear, at first blush, to be of minor moment, but the effects produced on the human target are of vital importance to military surgery, because the mere sharpening of the bullet's point has reduced its time of flight in 2700 yards from 2 seconds to 1.6 seconds, and it arrives with a velocity of 1140 instead of 940 feet per second.

Trajectory, or curved line of flight, of the small-calibre bullet is so much flatter than that of the older form that, at all ranges, it passes closer to the line of sight and greatly increases the danger zone. Velocity is the chief factor in the wounding power of the small-calibre bullet; the greater the velocity, the more severe the wound. Energy, or striking force, as the resultant of weight and velocity, represents the *real* damaging quality of a projectile, varying as the energy is distributed by its form. Energy is expressed in the formula:  $E = \frac{wy^2}{2}$ . Range

is important only when the velocity, weight, form, etc., of a projectile are known; then these ballistic data are of great interest because they reveal the energy or damaging force remaining in a projectile. The remaining energy of the American or German bullet, e.g., will drive it through the bodies of two men at 2000 yards and cause disabling injuries at twice that range.

The wound effects of small-calibre bullets at

various ranges are usually classified as follows: (1) explosive range from 0 to 500 yards; (2) perforating range from 500 to 2500 yards; (3) penetrating range from 2500 yards. The greater number of severe wounds is inflicted at a range of much less than 500 yards, as the terrific initial striking force of from 2 to 2.5 foot tons loses two-thirds of its energy within this range, although the bullet continues its flight for six times that distance. Ricochet shots, occurring as often as one in three, provide irregular elements which disturb any classification based on wounds made by undeflected bullets. Jacketed bullets are rarely deformed by striking the body; infrequent exceptions prove the rule. Every deformed bullet is caused by a ricochet shot.

Early experiments with the ogival blunt-nosed and the ogival sharp-pointed bullets on cadavers demonstrated their great destructive action. This was manifested by extensive laceration and blowing out of tissue at the wound of exit when, at close ranges, the bullets struck resistant tissue, as bone, and fluid-containing organs, i.e., stomach, bladder, and intestines. "Explosive effect," the misnomer applied to this phenomenon, suggests the action of the explosive bullet. The real cause is the imparting of the energy of the bullet to the wound fragments which become secondary missiles. The false interpretation of these manifestations had led, at the beginning of every recent war, to charges and countercharges of the use of explosive and dum dum bullets. Explosive bullets containing a charge and fulminate which causes them to explode in the wound with *real* explosive effects are no longer used in any army. Dum dum bullets, taking their name from a British arsenal near Calcutta where they originated, were first made with an uncovered soft-lead cylindrical-cupped extremity. Later the lead core of the bullet was exposed either by sawing right-angle cuts through the covering of the rounded extremity or by removing the jacket entirely from the nose. These bullets tear wounds frightfully, because they mushroom, flatten, and break up on impact, producing wounds like those of the explosive bullet.

As one shot in every three fired ricochets, it is impugning the intelligence of the enemy to accuse him of using either the explosive or the dum dum bullet when one-third of his missiles would become ineffective through disintegration. All nations signatory to the second Hague convention, excepting the United States and Great Britain, renounced the use of dum dum and explosive bullets. These missiles are used only against a fanatical foe, charging in masses small bodies of troops, because the stopping power of the normal military bullet is not great enough to check promptly such an advance.

Artillery wounds are inflicted by two classes of projectiles—shrapnel and shell. A modern shrapnel consists of a thin-walled steel cylindrical envelope with a thick bottom containing, like a shotgun cartridge, a charge of powder behind a number of naked lead balls. The top of the envelope is closed by an ogival head carrying both time and percussion fuses. The former provides for the ignition of the powder charge at the time estimated for the projectile to reach the desired point, when the contents of the envelope are projected like the charge of a shotgun *without bursting the envelope*. The

percussion fuse is designed to explode the shrapnel on impact only when the time fuse fails. The shrapnel used in the field guns of most armies is approximately 3 inches in calibre and contains about 300 balls of about 0.5 inch diameter. A shell, on the other hand, is a thick-walled steel capsule filled with high explosive and armed with a percussion fuse to cause explosion only on impact. Shell wounds are produced by the flying fragments of the shell itself.

Shrapnel wounds are like those of the old round leaden musket balls. Because of their low velocity they are more frequently lodged in wounds than are rifle bullets. Shell wounds as a class are much less frequent but far more severe than shrapnel wounds. Shell fragments cause complete destruction near the bursting point, but effect less damage in more distant zones. Both shrapnel and shell wounds are usually infected, because the missiles carry into the wounds pieces of clothing and other foreign matter. The danger of infection is much increased because of the greater extent of laceration. Wounds by bayonet, sabre, and lance occur so infrequently as to be of minor interest. During the Franco-Prussian War there were only 600 wounds by cold steel among 98,000 wounded. Grenades, thrown by hand, rifle and trench mortar, a revival in late wars of an earlier practice, recently have been used to a conspicuous extent in Flanders and France. Their wounds differ in no material particular from those of shell fragments and subterranean mines.

Among the most conspicuous innovations of the Great War is the use of asphyxiating gases. Two kinds have been employed. One, the trench gas, is emitted from cylinders containing the vapor under pressure; this consists chiefly of chlorine. The nature of the other gas or gases thrown out by asphyxiating shells has not been determined, but organic compounds of bromine have been identified. The gases, being heavier than air, settle in trenches and depressions of the terrain. Effects produced are ocular, respiratory, and gastric irritation and general toxic action. Radiography, which has always contributed so much more to military than to other branches of surgery, has been further adapted to the treatment of gunshot wounds by a recent method of finding missiles by direct view on the radiographic screen. As pus infections have been more successfully controlled by modern methods, the two most resistant conditions, tetanus and gas bacillus infections, have become more conspicuous in late wars. Although there is an antitoxin for tetanus, it is efficient only when administered as a prophylactic.

Gaseous gangrene is the result of an infection with a bacillus which grows in the recesses of a wound, developing a virulent toxin and a gas which inflates the tissues. Absorption of the toxin is so rapid that death may intervene in a few hours or days. Incision, drainage, antiseptics, and even amputation often fail to save life. No specific remedy has been found for the disease, now the most feared and fatal of all wound complications. Treatment is based on antiseptic measures.

For the prevention of wound infection Sir Almroth Wright has presented new principles and recommended new practice. The most concrete and practicable method, perhaps, is that advised by Carrel of the Rockefeller Institute,

as the result of recent experience in France, who urges the use of Dakin's special sodium hypochlorite solution in the early treatment of all gunshot wounds.

Theatres of operation have much to do with the incidence of various surgical conditions. In the French retreat from Moscow and in the Crimea, frostbite and resultant gangrene played an important part in the surgical history of those campaigns. Densely populated districts, where intensive cultivation and fertilization provide a congenial habitat for bacterial flora, offer favorable conditions for wound infections, especially when military operations conduce to contamination of wounds from the soil. On the other hand wound infections are more rare in campaigns in sparsely settled countries. Makins says that in the Anglo-Boer War he knew of only one case of traumatic tetanus.

In general it may be said that wound treatment should be directed primarily to the prevention and control of infection with a secondary regard for the correction of deformities. The latter should follow after resolution is established. Conservatism to a degree that seems beyond the experience and conception of civil surgeons should always be practiced, as urged by Delorme, who says: "In order to avoid the excess of operative measures practiced in recent wars, I am impelled to enjoin all military surgeons to practice almost uniform conservatism." Consult Edmond Delorme, *War Surgery* (New York, 1915). See *AMBULANCE; HOSPITAL, Military Hospitals; HYGIENE, Military Hygiene*.

**SURGERY AND MEDICINE DURING AND AFTER THE EUROPEAN WAR.** At the outset (1914) the medical body in the armies looked upon military surgery as crystallized through the lessons of the Russo-Japanese, Balkan and other recent wars. These lessons affected all military activities, whether of surgery proper or wounded-transport and during the earliest weeks the predictions of surgeons that war would find them quite prepared seemed to be fulfilled. The sudden change to trench warfare from the North Sea to Switzerland with the substitution of artillery for rifles, however, had evidently not been duly considered in the medical programme; such lessons as could be gleaned from siege warfare proved of no value. War now meant guns of large calibre and high explosive shells. A new type of wound now became universal—extensive, lacerating, containing fragments of projectile, bits of clothing and dirt. Adjacent tissues not actually wounded were devitalized. Such wounds and tissues almost inevitably became infected. Moreover, those who were constantly menaced by such injuries were living and fighting in the most unsanitary surroundings underground where personal hygiene was impossible. The dampness favored various medical diseases which would have developed without battle—respiratory and other affections which prevail under exposure to wet and cold. The presence of vermin in addition to the personal discomfort made the spread of three or four serious diseases possible. Transport was unduly difficult because in addition to all intrinsic hardships the enemy shelled the back areas and lines of communication. A system of nocturnal transport had therefore to be put into effect and was of course highly inefficient, judged by comparison. Infection was favored by the delay, and the resistance of the wounded was also

lowered by exposure and privation. An error which was eventually recognized and corrected was the early effort to relay the wounded from hospital to hospital until the base hospitals of the home cities were reached. Patients whose wounds were doing well were not infrequently seen to relapse under this system of transport.

In addition to ordinary wound sepsis other forms of infection inhered in the soil of France causing an unusual amount of tetanus and the so-called gas gangrene, which was not much known, being extremely infrequent in civil life. The issue in the most menacing cases depended largely on the thoroughness of the first dressings which made it imperative that these be practised as soon as possible. The scale on which this war was waged also inevitably led to shortcomings in service and the principle of salvage had to be exploited to the full. Only those who might be saved to fight again received the best attention. The slightly injured and moribund alike had to give way to the other sufferers.

The struggle narrowed down to a battle with infection in its widest sense. The standard of personal hygiene was elevated and chiefly by shorter shifts of fighting, which made it possible to take more nourishment, to change clothing and to rest. The trenches were drained and otherwise made more sanitary, and attempts were made to rid the troops of vermin at regular intervals. The four gradations of first aid, regiment dressing stations, field and evacuation hospitals were moved closer to the trenches. When a wounded man was transferred it was sought to move him once for all.

The direct struggle against infection began with the application of antiseptics of the bactericidal type, but solutions of chemicals were insufficient in themselves and mechanical measures of all kinds were then superadded. The first aim was to lay the wound completely open and thus facilitate the application of chemicals and permit drainage. But one of the first fruits of experience was that wounds even when soiled could be safely closed, if no time was lost, by the simple measure of excising the contaminated tissues. The limit was 8 or 10 hours after injury and naturally only certain localities were suitable for such heroic treatment. Not only contaminated but devitalized tissue had to be included in the excision and the rule was to cut through sound tissues. The clean wound thus made was now sutured completely, this act of suture involving restoration of the continuity of tendons, nerves and muscles. This procedure was also adapted to compound fractures. Immobilisation of all wounds was found advisable and splints were used in flesh wounds as well as fractures. About ten days elapsed in these cases before transportation was allowed; and if the wounded had to be moved prematurely suture was deferred until the next station had been reached.

In wounds inflicted more than ten hours before the period of dressing and in those wounded who must be transported before the expiration of ten days the method of deferred suture was practised. Sometimes the surgeon took a chance and closed a wound as late as 24 hours after injury. Closure was however only tentative and contingent on the result of a bacteriological examination. If this research had a favorable result the sutures, which were already in place, were tied. This resource is known as primary delayed suture. In certain

exceptional cases, as shown by the bacteriological control, closure is practicable after 48 hours. The results of primary closure comprise 90 per cent of successes and in delayed primary closure 60 per cent. These figures do not include compound fractures in which under the most favorable circumstances successes are 50 per cent.

This highly successful lesson of the war should be classed under a sepsis because bactericidal substances bear no part in the treatment. Under civil practice conditions it should be even more successful and to withhold it from a patient seems a step backwards. But antiseptics also had its sphere of usefulness in all wounds which for any reason were ineligible to the measures just narrated. Excision of the wound is often impracticable. There is need of a chemical antiseptic and the Carrel-Dakin solution was found to be superior to any other of the many tested. It is non-irritating, germicidal and free from any injurious effect. It is a solution of a little less than one-half of one per cent of sodium hypochlorite in water and everything depends on its standardisation. The technique of generating, preserving and testing this preparation is too long for reproduction here but the aim is to have available a relatively stable solution, because in the absence of certain standards the results would not only be negative but harmful. It is this tendency toward instability that delayed the general adoption of the solution—many of the early reports having been unfavorable. The solution acts in part by liberating nascent chlorine from the hypochlorite and has the not less valuable secondary action of dissolving pus and necrotic tissue. This property is, or might prove to be, in one way a source of weakness, for the solution also dissolves fibrin and tends to favor hemorrhage. But for this reason complete hemostasis is secured before the preparation is applied.

But even when used in its ideal form the Carrel-Dakin solution must be adjusted to other methods of wound treatment. The injury must be mechanically prepared, just as in the wound which is closed at once, although naturally by a technique quite different. Much depends on the type of infection. In one extreme we find a wound which is suppurating freely and at the other one which does not suppurate at all, the pus being pent up beneath the surface—the so-called phlegmon. Between these extremes are all intermediate gradations. The freely discharging wound causes a minimum of constitutional disturbance while the phlegmon is attended by marked general symptoms. In the pure phlegmonous type excision is out of the question just as in the opposite condition it is usually unnecessary. The indication is to expose all the deep or concealed foci of infection without causing additional infection. It is better to err on the conservative side and to be content with multiple superficial incisions, removal of foreign material and the like. In the freely suppurating wound drainage may be facilitated by exposing pockets, and shreds of dead tissue may be excised; in selected cases it will be safe to excise the wound outright as in recent wounds.

After preparation of wound surfaces the solution is applied by irrigation technique. The wound must be flooded completely and a special apparatus was employed by means of which the recesses of a deep lesion could be flushed out,

this involving the use of perforated tubes resembling drainage tubes. In the average large wound a number of these Carrel tubes were held in place by a loosely packed gauze dressing. The experience and judgment required in selecting the proper tubes in the proper numbers were such that instruction was necessary and in the absence of oral and practical demonstration printed directions of the most minute character worked out by physical laws were available.

This standardisation of treatment is of course indispensable in all military surgery. However bland and innocuous to wound surfaces if properly used the Carrel-Dakin solution is extremely irritating to the skin and it is necessary to protect carefully the latter with vaselinated gauze. This fact alone is sufficient to set at rest the statements sometimes encountered that the solution was but little more than sterile water which worked mechanically. It is also not rare to encounter the statement, even from high sources, that the solution and a number of analogous preparations act chiefly by provoking a flow of lymph from the wound surface which washes out mechanically all of the germ life, foreign detritus and devitalized tissue.

Any attempt to give the entire technique of the use of this solution in infected wounds would be beyond the scope of this article. It is readily demonstrable that the first effect of the fluid is to paralyze, without actually destroying, the germ life, for about two hours. Hence the original continuous irrigation was replaced by intermittent exhibition, kept up throughout the night — for despite assumptions to the contrary sleep was not materially interfered with. Naturally the tubes were not disturbed in intermittent irrigation. There were regular intervals for dressing these wounds and the perfection of technique was such that the entire dressing, tubes and all, could be brought away *en bloc*, and without unnecessary delay. According to the degree of success of the treatment the surface of the wound varied in appearance, the ideal being one of healthy granulation, without pus or smell. Partial failure was apt to be due to incomplete mechanical preparation of the wound, as shown by the presence of small pus pockets.

In dressing the wound for this second time the first step is cleanliness, the wound surface being flushed openly and the granulating surface scrubbed gently with soap or gasoline. The second dressing ordinarily occurs 24 hours after the first and is intended to last another 24 hours. By means of coöperative effort the second insertion of tubes and application of dressings can be accomplished rapidly. The patient in these cases seldom feels pain and sometimes can help with the change of dressings.

The course of wound healing can be computed and foretold with mathematic precision. By means of a special planimeter the wound surface can be accurately measured at the start and at intervals afterwards and the rate of healing and increments of healed surface determined and foretold, while a curve of healing could be plotted. These curves are naturally quick to show a disturbance of healing, as from interference with daily treatment or intercurrent affection. In the long run these interruptions seem to be adjusted and healing need not be prolonged. At each change of dressing a bacterial count is made but only in case the wound cleans up as it should. A smear for the study

of germ life can only be taken after the wound is quite clean, so that in practice it is obtained after the scrubbing of a wound in the course of changing the dressings. If the count is 50 to the microscopic field this is to all intents and purposes no count. The wound is foul. Anywhere from ten to fifty specimens are examined at a time and an average computed. Under successful treatment a count of one or two per field should be reached by the second dressing. After that epoch the count diminishes gradually and when one germ only appears in five fields on two successive daily examinations the wound is surgically clean, although the ordinary surgical streptococcus even with this frequency would be a menace. It is claimed that the latter never occurs in this minimal degree, but in any case this low bacterial count is a guarantee of an immune wound. In the final analysis the microscopic finds may be disregarded in favor of the clinical result.

Experience has taught that under the most favorable auspices ordinary wounds become clean in from 5 to 8 days while very large or otherwise extraordinary wounds require a proportionally longer time, as two weeks or more; but even compound fractures heal completely in four weeks. In speaking of surgical cleanliness some surgeons would not stop at a mere count but would go to the extent of attempting a culture from the wound secretions. This seems to be an unnecessary refinement.

Thus far we have been discussing only the cleansing of the wound and not its cicatrization. The two may be readily confused but all figures thus far quoted refer to cleanliness and not healing proper. All of this cleansing is only a preparation for closing or suture of the wound surface. If not closed it could only heal after a long period of cicatrization. A surgically clean wound has reached the stage at which it may be safely closed, yet in civil surgery we do not speak of closing wounds which have been left to granulate for one or two weeks. In warfare it is different for these men are needed again at the front.

After application of secondary suture of these clean wounds eight days are required for healing. In that time healing could go far without suture, at least in wounds up to a certain size. In small wounds there would be no time-saving; and therefore in a large number of cases there is nothing gained and something to lose if we attempt to close these wounds by secondary suture. This operation means giving ether or chloroform and excising the new granulating surface, the new wound being closed by interrupted suture. No so-called tension sutures are permissible; if tension is required undermining or plastic work is the resort. The dressing in secondary suture which includes the use of splints need not be disturbed for a week.

All wounds treated by the Carrel-Dakin method heal with a minimum of scarring. Massage and other manipulations used ordinarily in making the scar supple and thus accelerating functional recovery are forbidden, experience teaching that new inflammation may at times be lighted up. Less instable solutions which liberate chlorine have been sought, but none has been found with the combined advantages of the hypochlorite. Writing in 1919 on modifications of surgical practice resulting from war Dr. Wm. J. Mayo mentions only the original Carrel-Dakin solution. Nevertheless the use of chloramin T

and dichloramin T, both devised by Dakin himself, has given very favorable results.

In the case of tetanus as a possible complication of wounds no special technique was required for every wounded man received preventive injections of serum. In order to prevent the development of late tetanus four injections were given one week apart. If after this period it became necessary to operate on a wound or its scar, further injections were given. When gas phlegmon or gas gangrene threatened as a complication of wounds everything depended on a knowledge of the natural history of this form of infection which enabled the surgeon to recognize the earliest symptoms and apply prompt and energetic treatment. At this period the infection is in its dormant phase; the wounds appear dry and pale and there is a peculiar behavior on the part of the exposed muscular tissue. Gas infection is in fact exclusively infection of muscle tissue with gas-forming bacteria. Even the gas in the loose subcutaneous tissue is said to have escaped from muscle. The earliest known formation of gas in the latter is 5 hours after injury. The peculiar behavior of the muscles comprises the following: Brick red color; failure to twitch when pinched; failure to bleed when pricked; absence of striation (this is not seen in simple gangrene) and peculiar X-Ray appearance. The close of this initial phase is marked by distention of the muscle with accumulating gas and the beginning of actual mortification with its characteristic odor. Constitutional reaction is also in evidence including subnormal temperature and rapid pulse. During this second stage the patient may have a fighting chance. When actual bubbles begin to form in the tissues the third stage begins, and the local and general infection spreads so rapidly that the patient is practically doomed. The infection may produce death in 15 hours, so rapidly may the different stages succeed one another.

At the beginning of the war before the nature of the process was understood the mortality from gangrene was frightful. Eventually the treatment was standardized as follows: As soon as the diagnosis had been made in the manner stated the patient was anaesthetized and the suspected muscle at once excised, going a little into the sound tissue; this in addition to the usual technique of recent wound treatment. Thorough cleansing and hemostasis are required in any case because these wounds are treated like others with the Carrel-Dakin solution. Should the wound not respond to this management amputation is the rule and this is naturally the management of untreated cases which have progressed beyond the first and second stages. The medicinal treatment consists in giving plenty of bicarbonate of soda to ward off the acidosis which always develops in these cases and in the use of certain antitoxins.

The belief that the war revolutionized the treatment of burns is not true and this false impression came about through commercial propaganda and the free use of the lay press. The use of paraffins of low melting point merely proved to be a valued accessory to measures already in vogue. There is no substitutive paraffin treatment and paraffin can do nothing that other substances cannot do as well. Dichloramin T for example is as good a remedy for routine use.

The new affection known as trench foot requires a word of mention. It is of the same

class as ordinary chilblain and frostbite but differs from both. There is no itching as in chilblains and while frostbite is a simple lesion which appears in dry cold, trench foot is determined by a variety of factors as wet, medium cold temperatures—not the intense cold which causes frostbite—tight or ill-fitting boots, neglect to change the foot coverings, etc. In an advanced stage with production of gangrene there seems little or no difference between frostbite and trench foot. The chief subjective symptoms are burning, numbness and tingling and the feet are red or livid and insensible to pin prick. In not a few of these cases tetanus was a complication. The chief preventive was foot hygiene including the use of a good foot powder. No other treatment was required than rest save when actual gangrene had developed. Amputation is not required and the slough is allowed to separate of itself.

The plastic restorative surgery of the face so much practised in and after the war involved no new surgical principles, and this is also true of the surgery and prosthesis practised on war cripples. Some of the lessons of the war summed up by William J. Mayo in 1919 (*Southern Medical Journal*, January number) are as follows. The first is that the young and robust soldier has a great tolerance for certain surgical measures which would be quite inappropriate to the ordinary civil hospital patient who is often diseased, feeble or aged. Another lesson is the distinction between infected and merely contaminated wounds. The latter in civil surgery have been regarded as practically infected. A merely contaminated wound may be rendered surgically clean which is impossible once true infection has occurred. In the border-line case one may give the patient the benefit of the doubt by a temporary dressing and should the wound prove to have been merely contaminated, it may be closed by delayed suture. In abdominal surgery a merely contaminated wound can be cleansed and closed without drainage. In rare cases gauze drainage is used to check hemorrhage, to be removed in 24 to 48 hours with subsequent closure of the wound. Dr. Mayo gives most unqualified endorsement of the Carrel-Dakin treatment of infected wounds. This with the practice of excision and closure of recent wounds became standardized in all the Allied armies before the end of the war. The French surgeons are given credit for the innovations for although Carrel is an American by adoption and Dakin English, it required the judgment of the French constituted authorities to sanction the general use of these resources.

A third lesson to be derived from war surgery is the management of surgical shock. Whatever its actual nature—and it may be seen in the absence of all loss of blood—it is best to think of it as dependent largely on the wound hemorrhage. At the same time there is a type of pure hemorrhage which differs entirely from the picture of shock. In combined shock and hemorrhage the treatment found most efficacious did not differ save under certain circumstances from that of civil surgery. Hemorrhage was checked in the usual manner during the dressing of the wound and if extreme, transfusion was added. Morphia was given with dry warmth, hot drinks and the use of bicarbonate of soda and glucose, best per rectum. Saline infusion proved to be no substitute for transfusion in military surgery, and owing to the leaky condition of the cap-

illaries much of the infusion escaped from the blood vessels into the tissues. Mayo recommends instead the 6 per cent solution of gum arabic in salt solution used originally by British surgeons. This is one of the developments of war surgery applicable to civil practice. The surgeon is recommended to carry in his bag a half pound of gum acacia and a funnel, tube and needle for intravenous injection. Salt, water, heat and flannel for straining may be always found at the patient's home. This resource is of no use in bloodless shock.

The fourth lesson learned from the war according to Mayo relates to choice of anaesthetics. Ether by the drop method has proved its worth. Local anaesthetics, blocking, etc., were not much used at the front, but were in much demand in base-hospital work. The value of the nitrous oxide-oxygen mixture is offset by the cumbersome of the apparatus, so that its use is also largely restricted to work at the rear where it was found especially valuable in the removal of certain dressings. Spinal anaesthesia does not seem to have found any field in military surgery.

The subject of the fate of the war cripple and blind hardly belongs in the present section. The problem of the physical defective—how to lessen his disability and secure the means of self-support—has always been with us, although it became greatly intensified as the result of the war.

Under the head of war medicine as distinguished from surgery may be mentioned certain conditions which from their novelty received much space in the lay press although they make up but a small fraction of the total. Here belong gas poisoning and its remote consequences and shell shock. In Hurst's *Medical Diseases of the War* 1918, a work of 318 pages, gas poisoning occupies but 8 pages and shell shock 15. Shell shock was but one of a large number of neurological affections or war neuroses, others being neurasthenia, hysteria, epilepsy, insanity, paralysis, speech disorders, disorders of vision and hearing, soldier's heart, etc. Shell shock was the result of the explosion of powerful shells—so-called air concussion which caused no visible wound. The gases liberated were also toxic, so that in these victims there was a component of gas poisoning. The phenomena of shell shock comprise the primary concussion of the brain or spine with the immediate consequences, and to these must be added the remote effects which agree fully with those of traumatic hysteria following certain severe injuries in peace times. The shell-shocked man must be allowed to rest for some days but if this rest period is prolonged the condition will be aggravated instead of benefited. Hence, save in the worst cases in which complete stupor was present, the patient was roused daily for a short time and incidentally given a bath. Active exercise begins with the disappearance of the headache or backache. The after phenomena comprised under hysteria show the greatest variety and are familiar to the public through the numerous claims for compensation made by victims of railway accidents and industrial injuries. Victims of shell shock who are long incapacitated may be grouped with the physical cripples in the problems of restoration, education and occupation.

In regard to gas poisoning this was a serious problem before the introduction of respirators. In this early period 5 per cent died within 48

hours and an additional 1 or 2 per cent later from pneumonia. Lethal gases in addition to their conquest by respirators gave way largely to the merely incapacitating forms which did not cause persistent lesions. In regard to the relation of respiratory gassing to the subsequent development of tuberculosis this is elusive and a problem which concerns the individual victim rather than the troops collectively.

About one half the space required for the consideration of military medical diseases and their sequelae is devoted to nervous affections and of the balance most of the space is given to ordinary camp diseases as distinguished from epidemics. These are very largely alimentary infections as dysentery, paratyphoid fever and diseases of the liver including hepatic abscess and forms of epidemic jaundice. Others which occasionally appear, as scurvy and beri beri, are due to insufficient rations. Diseases peculiar to the recent war or first recognized at that period are trench fever, a form of nephritis and soldier's heart, although the latter may be grouped among the neuroses. The form nephritis is relatively benign, while trench fever, presumably transmitted by body lice, is without mortality and may therefore be passed over. Soldier's heart is due to overexertion, whether physical or mental, and seldom has led to permanent retirement of the victim from the ranks. For a consideration of the epidemic diseases of the war the reader is referred to the War Supplement. Chief references: Allen Rice, *Surgical Lessons of the War* (1919); A. F. Hurst, *Medical Diseases of the War* (2d ed., 1918).

**SURGICAL ASSOCIATION, AMERICAN.** A society founded in 1880 for the primary purpose of cultivating and improving the science and art of surgery. The active membership is limited to 125 fellows; the honorary membership to 25 fellows. An applicant to be eligible for fellowship must be 30 years old, a graduate of five years' standing from a recognized medical college, and have an established reputation as a practitioner, author, or investigator. The meetings of the association are held annually. Every third year the association joins with the constituent associations of the Congress of American Physicians and Surgeons in a meeting held in Washington, D. C. An annual volume of *Transactions* is published.

**SUR'HAY.** See SONGHAY.

**SUR'ICATE.** The meerkat (q.v.).

**SURIGAO,** sŏr'ĕ-gā'ŏ. A province of north-east Mindanao, Philippine Islands (Map: Philippine Islands, E 6). Area 6988 square miles. The greater part is covered with forests, and the river forms almost the only means of communication, most of the towns being situated on its banks. Cotton, hemp, rice, sugar, and tobacco are raised, and betel nuts and coconuts are exported. Pop., 1903, 115,112, mostly Visayans. The capital, Surigao, had (1903) 7749 inhabitants.

**SURIGAO, STRAIT OF.** The strait connecting the Sulu Sea with the Pacific Ocean, extending between the island of Mindanao on the south and the islands of negros, Cebu, Bohol, Leyte, and Samar on the north (Map: Philippine Islands, E 5).

**SURINAM,** sŏr'i-nām'. A river of Dutch Guiana. It rises in the south-central part of the country, flows northward a distance of 400 miles, and empties into the Atlantic Ocean through an estuary 3 miles wide, on whose shore

lies the town of Paramaribo. It is navigable 40 miles for the largest vessels and 100 miles for ships drawing 10 feet. Near its mouth it is joined by the Cottica River, a navigable channel running 100 miles parallel with the coast and connecting with the mouth of the Maroni.

**SURINAM.** A Dutch colony in South America. See GUIANA.

**SURINAM BARK.** See ANDIRA.

**SURINAM TOAD.** See PIPA.

**SURKI.** See CEMENT.

**SURMULLET** (OF., Fr. *surmulet*, from *sur*, *sour*, reddish + *mulet*, dim. of *mulle*, from Lat. *mulius*, red mullet). One of certain species of mullets found for the most part in the tropical seas. The striped red surmullet (*Mullus surmuletus*), attaining a weight of six to eight pounds, is sometimes abundant on the coasts of Europe. A very similar species (*Mullus auratus*), about 8 inches long, occurs along the Atlantic coast of North America, particularly towards the south. See Plate of MULLET AND ALLIES.

**SURNAME** (OF., Fr. *surnom*, from ML. *supernomen*, from Lat. *super*, over + *nomen*, name). In modern usage, the family name, as distinguished from the given or individual name. Many are based on personal peculiarities, as William Rufus or *red*, John Lackland, and were originally mere epithets. Another class is patronymic, indicating descent, as Johnson, Williamson. This form of surname prevailed especially in Scandinavian countries, surviving in Denmark until about 1850, when it was replaced by the system of family names. For other kinds of surnames, see COGNOMEN; NAME.

**SURPLICE** (OF., Fr. *surplis*, from ML. *superpellicium*, surplice). A linen vestment worn in the Roman Catholic church by all ecclesiastics in choir except the officiants of the mass, and by the clergy of the Anglican communion; also, in both churches, by laymen and boys who sing in the choir or assist at the altar. The shape of the vestment in mediæval days was long and flowing; the modern tendency has been to reduce its size so that it usually comes little below the waist. The Italian name *cotta* is frequently applied to the modern vestment. See Plate of COSTUME, ECCLESIASTICAL.

**SURRATT**, sür-rät', MARY E. (c.1817-65). An American woman who became involved in the conspiracy against the life of Abraham Lincoln. She was born near Waterloo, Prince George Co., Md., and about 1835 married John H. Surratt. In 1862 Mrs. Surratt went to Washington and opened the boarding house which became the meeting place of the men who plotted to kill President Lincoln and other members of the government. After Lincoln's death Mrs. Surratt was arrested and, with three of Booth's accomplices (see BOOTH, JOHN WILKES), was tried and convicted by a military commission appointed by President Johnson. The sentence of death by hanging was carried out at Washington on July 9, 1865. During the trial doubts as to Mrs. Surratt's guilt were expressed, and a long controversy in the press followed, the weight of opinion inclining in her favor. It was said that a majority of the members of the military commission had signed a petition for clemency to President Johnson and that this petition was withheld from his knowledge, but this was vigorously denied.

**SURRENDER.** In law, the giving up or abandonment of an estate for life or years in

real property to the person next entitled to the remainder or reversion, with intent to merge the lesser estate in the greater. This differs from renunciation (q.v.), which is practically the refusal to receive an estate to which one is legally entitled. A valid surrender can be made only by an adult person of sound mind. Under the Statute of Frauds in most States a surrender in fact, i.e., by agreement, can be made only in writing, where the unexpired term of the lease is greater than could be created by parol. Thus, the mere cancellation or destruction of the instrument creating the estate will not operate ipso facto as a surrender. However, a surrender may take place by operation of law. Thus, where the landlord accepts another person as tenant; where the landlord takes possession of the premises to his own use; or where the tenant accepts a new lease for the same premises, these acts will be construed as a surrender by operation of law. The legal effect of a surrender is to terminate the relation of landlord and tenant and to discharge the latter from liability for future rent, though not for rent already accrued. See LANDLORD AND TENANT, and authorities there referred to.

**SURREY.** An inland county of southeast England (Map: England, F 5). Area, 758 square miles. Pop., 1901, 519,766; 1911, 676,027. The surface is hilly and diversified, with a north slope towards the Thames. The principal streams are the Mole and Wey, tributaries of the Thames. The north half of the county along the valley of the Thames is fertile, though little over half of the land in the county is cultivated, hops, wheat, and the ordinary crops being raised; market gardening constitutes a lucrative industry. In the west and southwest the land is to a great extent covered with heath. The numerous manufactures include silk, cloth, leather, paper, pottery, and beer. The varied and picturesque scenery of the county is responsible for the fact that it has become a great residential district for London business men. Consult *Victoria History of the County of Surrey*, vols. i-iv (London, 1902-12), and J. S. Ogilvy, *Pilgrimage in Surrey* (2 vols., New York, 1914).

**SURREY, EARL OF ARUNDEL AND.** See FITZ-ALAN, THOMAS.

**SURREY, HENRY HOWARD, EARL OF** (c.1517-47). An English soldier and poet, son of Lord Thomas Howard, affirmed third Duke of Norfolk. His youth was spent in France and at the court of Henry VIII, and he received a careful classical education. He was made Knight of the Garter in 1541 and in 1543 joined the English army in France, where by his prowess he gained the title of field marshal. He captured Boulogne, was made its Governor, and gained other victories, but was recalled to England after slight reverses at Saint-Etienne. His influence at court was no longer so powerful as in the life of his youthful friend and companion the Duke of Richmond, Henry's natural son, and charges of treasonable ambition were constantly urged against Surrey and his father by the Hertford faction. In 1546 the two were arrested; Norfolk was sent to the Tower, and Surrey, on trivial charges, was beheaded in 1547. Though not primarily a man of letters, his work in that field left a more abiding impression than his soldiery. He wrote amatory verses and elegies, but his service to English literature lay in the insight with which

he enriched its poetry by the introduction of new verse forms. His translation of two books of the *Æneid* gave the language its most powerful and characteristic poetic form, blank verse; and the sonnet which Shakespeare used, consisting of three quatrains and a couplet, was also introduced by Surrey. The best-known edition of his verse and that of Wyatt, including a memoir, is by G. F. Nott (London, 1815-16: new ed., 1871); there is also the Arber reprint of *Tottel's Miscellany*, in which the work of both of them first appeared. Consult also an essay in J. W. Hales, *Folia Literaria* (London, 1893).

**SURROGATE** (Lat. *surrogatus*, *subrogatus*, p.p. of *subrogare*, *surrogare*, to substitute, from *sub*, under + *rogare*, to ask). A judicial officer having jurisdiction over the probate of wills, the administration and settlement of decedents' estates, and in some States the power to appoint and supervise guardians of infants and other legally incompetent persons. As the derivation of the name indicates, a surrogate was formerly the substitute or representative of another official. Originally in England the ecclesiastical courts had jurisdiction of all the matters above mentioned, and as their business increased it became necessary for the bishops to delegate some one to act in their places. These substitutes were at first ecclesiastical, and at a later period lawyers, and were known as surrogates. In 1857 the probate jurisdiction of the surrogates was transferred to the Court of Probate and Divorce.

Prior to the Revolution the governors of the various American Colonies were accustomed to appoint surrogates to represent them in matters of probate and administration of estates. In New York and several other States to-day the surrogate of a county is an independent judicial officer. The incidental jurisdiction of the surrogate generally extends to contests of wills and controversies over the descent and distribution of property of decedents. Surrogates exercise a close supervision over the conduct of guardians' affairs, and the latter may apply to them for advice in case of doubt on any matter pertaining to their trusts. Proceedings before a surrogate are conducted with practically the same formality as in other courts. An appeal from the decisions of surrogates will lie to appellate courts. Surrogates correspond to probate judges and judges of widows' and orphans' courts in some States. See COURT; PROBATE COURT; and consult the authorities there referred to.

**SURTEES**, sŭr'tēz, ROBERT (1779-1834). An English antiquary, born at Durham. He graduated B.A. from Christ Church, Oxford, in 1803, then studied law at the Middle Temple. In 1802 he settled on the family estate at Mainsforth in the County of Durham. Surtees devoted his life to his *History of Durham* (vol. i, 1816; vol. ii, 1820; vol. iii, 1823; vol. iv, ed. by James Raine, 1840). This is a careful and exhaustive work, readably written. Surtees was also an adept at composing ballads which were playfully palmed off as ancient. Scott himself was deceived by *The Death of Featherstonehaugh*, which was inserted in the *Minstrelsy of the Scottish Border*. As a memorial the Surtees Society was established in 1834 at Durham for publishing unedited manuscripts bearing on the history of the northern counties of England from the earliest period to the Restoration.

Consult G. Taylor, *Life of Surtees* (Surtees Society, Durham, 1852).

**SURTEES**, ROBERT SMITH (1803-64). An English sporting novelist, born in Durham and educated for the law. In 1832 he helped to found, and for five years he edited, the *New Sporting Magazine*, to which he contributed (1832-34) humorous papers chronicling the sporting experiences of a cockney grocer. Collected as *Jorrocks' Jaunts and Jollities* (1838) and illustrated by "Phiz," these sketches had an immense vogue. This volume suggested the original plan of *Pickwick Papers*. In *Handley Cross* (1843) Jorrocks reappears, this time as a master of hounds. Surtees wrote various other books on the same order, most of them illustrated by "Phiz" or John Leech. Consult the memoir prefixed to the London, 1869, edition of *Jorrocks' Jaunts*, and W. P. Frith, *John Leech* (2 vols., ib., 1891) passim.

**SURVEY**. See COAST AND GEODETIC SURVEY, UNITED STATES; GEODESY; GEOLOGICAL SURVEY, UNITED STATES; SURVEYING.

**SURVEYING** (from *survey*, from AF. *surveer*, *survoir*, from Lat. *supervidere*, to overlook, oversee, from *super*, above + *videre*, to see). The art of ascertaining by measurement the shape and size of any portion of the earth's surface and representing the same on a reduced scale on maps in a conventional manner, or the reproduction on the ground of a predetermined line or lines, as for the construction of a canal, railway, bridge, or other structure for which plans have been drawn. The art of surveying or the measurement of land is probably as old as civilization. According to Herodotus the science of surveying, which is nothing more or less than practical geometry, originated in Egypt, where it was necessary accurately to reestablish each year the land boundaries obliterated by the inundations of the Nile.

The early history of surveying is the history of geometry, and all early textbooks invariably treated the two together. The first treatise on surveying extant is that of Hero of Alexandria (c.130 B.C.). In all times and in all civilized countries surveyors have been important public functionaries and were essential officers in all military campaigns or conquests. Surveys must be made preliminary to undertaking any kind of civil engineering or architectural construction; consequently surveying is a recognized branch of civil engineering.

Surveys are broadly separated into two classes, determined by the extent of the area surveyed or the purpose for which the survey is made. Plane surveying includes all surveying based on the assumption that the earth's surface is a plane. When the survey is of small areas or of a line or narrow belt of country, as for a railway, this assumption causes no serious difficulty. However, it is obvious that there is an error even in the smallest survey executed according to the rules of plane surveying. If two fields side by side be independently surveyed, the two planes supposed to represent them will not be extensions of each other, but will be slightly inclined to each other, the angle of their inclination being equal to the amount of the earth's curvature between their middle points. In the supposed case of two fields side by side the angle would be so slight as to be imperceptible, but if the two fields were separated from each other by 100 miles, their

inclination would be so great that the plane of one of them extended in the direction of the other, instead of coinciding with it, as it would if the earth's surface were a plane, would pass over it at a height of  $1\frac{1}{4}$  miles. A more accurate method, taking into account the shape and size of the earth, is geodetic surveying or geodesy (q.v.).

Plane surveying ordinarily includes besides land surveying, topographic surveying, hydrographic surveying, mine surveying, city surveying, and the measurement of earthwork or volumes of any material. Geological surveying is a development of topographic surveying in which the outcrops of the earth's rock formation are located and denoted on topographic maps. Geodetic surveying is a class by itself, as is also photographic surveying (q.v.).

#### PLANE SURVEYING

**Land Surveying.** Land surveys are made: (1) to establish certain monuments, corners, lines, and boundaries, so as to lay out and divide land; or (2) to identify and locate such monuments, lines, and boundaries after they have been established, as in all resurveys for location and area. In all cases of land surveying the boundaries and dividing lines are the traces of vertical planes on the surface of the ground, and the area is the area of the horizontal plane included between the bounding vertical planes. In other words, the area sought is not the real surface, but the horizontal projection of that surface. On the ground lines are marked only at regular intervals called stations or at the angles, points, or corners. The corner marks are called monuments and are usually of a permanent character, although anything from a mound of earth or a handful of buried charcoal to a cut stone with a copper bolt centre has been used.

For ordinary land surveying but two instruments are required, a chain or tape and an instrument for measuring angles or for determining the difference in direction between two or more intersecting lines. The simplest instrument for this purpose is a square or cross-staff, which gives two horizontal lines of sight at right angles to each other. By placing one line of sight coincident with one of the intersecting survey lines, at some convenient distance from the point of intersection, a right angle offset perpendicular to it from the other survey line may be readily established and measured. Thus, any acute angle may be measured by knowing the lengths of the two legs of the right triangle including it. The cross-staff, or some form of it, is one of the most ancient of surveying instruments. No radical departure was made from this method until the introduction of the magnetic compass, which was probably made use of by surveyors soon after its adoption by mariners.

The measurement of angles directly in degrees and minutes of circular arc did not come into vogue until about the sixteenth century. The combination of a magnetic compass with instruments for accurate angular measurement is a comparatively modern invention (c.1830). In using a magnetic compass the index of the dial is placed in the vertical plane of the line to be surveyed. The reading of the needle will then be the angle that the line makes with the magnetic meridian and is called the magnetic

bearing of the line. There are many inaccuracies arising from the use of a magnetic compass, not only from the irregularities of the needle according to the laws of terrestrial magnetism (q.v.), but from local attraction. It is no longer used except for reconnaissance or very rough work, but it is still universal practice to describe land by distances and bearings of courses. For this purpose the bearing of any starting course may be assumed, for it is evident that it is the difference in the courses which establishes the angles between lines, irrespective of whether the bearings are true or not. The true bearing of any line may be easily determined by observations on the sun, the pole star, Polaris, or any heavenly body whose position at the time of observation can be readily computed. This is called the determination of the azimuth of the line. The now universal surveying instrument is the transit. (See SURVEYING INSTRUMENTS.) Measuring the lengths and directions or bearings of survey lines is called traversing.

The simplest method of computing area is to divide the survey polygon into triangles. This, however, is cumbersome and requires many additional measurements. The method most used depends upon establishing the corners by a system of rectangular coördinates, known as latitudes and departures, which are readily computed by trigonometry from the lengths and bearings of the courses. Mathematical tables for simplifying these computations are called traverse tables. To illustrate the use of lati-

DIAGRAM OF A SURVEY.

tudes and departures reference will be made to the diagram, in which the lines  $A B C D E$  represent the boundary of a field of land whose area is required. Beginning at  $A$ , the surveyor proceeds around the field, obtaining the bearings and lengths of the lines  $AB$ ,  $BC$ ,  $CD$ ,  $DE$ , and  $EA$  one after the other in the order named. This being done he states these bearings and distances on paper, giving the figure  $A B C D E$  shown by the sketch. He next draws a meridian line  $NS$  through the westernmost corner of his boundary and computes the various perpendiculars shown by the broken lines. These per-

pendiculars are the latitudes of the several lines; thus, for line  $DC$ ,  $dD$  is the latitude,  $dC$  is the departure, and  $(fD + eC)$  is the double meridian distance. The following rule is used for calculating the area: twice the area of the figure is equal to the algebraic sum of the products of the double meridian distances of the several courses into the corresponding latitudes, north latitude being reckoned positively and south latitude negatively. Expressed symbolically, for the figure shown, this rule is as follows:  $2A = (bB + eC) Bc + (eC + fD) Dd - (fD + aE) Eg - (aE) Aa - (bB) Ab$ . It may often happen that one boundary of a field is not a right line, but is an irregular curved line such as the course of a stream  $CFB$  instead of by the right line  $BC$ . The area of this field is then the area of  $ABCD E$  plus the area of  $CFB$ ; the surveyor when measuring the line  $BC$  measures two or more perpendiculars such as  $ax$ ,  $yy$ ,  $zz$ , and  $vv$ , known as offsets and extending from the line  $BC$  to the stream. These perpendiculars divide the area  $CFB$  into a number of small areas each of which approximates closely a simple trapezoid or triangle whose area is easily determined and the sum of whose areas is the area of the total tract. There is of course a slight error in this method, but it can be made so small by an experienced surveyor as to be practically negligible.

The system of laying out the United States public lands furnishes a good example of the methods of laying out land on a large scale. This system probably was devised by Gen. Rufus Putnam, of Revolutionary War fame, and was first used in laying out the eastern portion of the State of Ohio in 1786-87. The reference lines employed in these public land surveys are in each case a principal meridian and a base line, the meridian running, of course, north and south, and the base line running east and west. From the principal meridian and its accompanying base line guide meridians are run north and south from the base line 24 miles apart, and standard parallels are run east and west from the principal meridian 24 miles apart. These lines are run with great care, making allowance for the curvature of the earth. Every mile is marked by a monument and is called a section corner, and every sixth mile has a different mark and is called a township corner. From each township corner on any standard parallel, auxiliary meridians are run north to the next standard parallel. Since these meridians converge somewhat towards the principal meridian, they will not be quite 6 miles apart when they reach the next standard parallel, and therefore, to run the next series of auxiliary meridians north, the start is made not at the points where the first series terminate, but at the 6-mile points previously marked off. Where the auxiliary meridians have been lined out, the land is divided into a series of strips running north and south and 6 miles wide. These are called ranges. The next step is to cut these ranges transversely by running east and west lines at 6-mile intervals. The land is thus divided into squares measuring 6 miles on each side. These squares are called townships, and each contains 36 square miles, or 23,040 acres. The next step is to run meridians and parallels 1 mile apart to divide the townships into 36 sections. Monuments are set at intervals of  $\frac{1}{2}$  mile on the lines to divide

each section into quarter sections. The quarter section is the smallest primary division of the public land surveys.

**Topographic Surveying.** The topography of a country is the collection of physical features which characterize it, and hence a survey intended to locate and map those features is a topographic survey. Ordinary land surveying takes into account only features which are relevant to the purpose of the survey and only those features which can be shown by horizontal measurements. Topographic surveying requires measurements in vertical planes as well. Otherwise it does not differ from ordinary land surveying except in instruments and methods. The basis of all topographic surveys is a line or network of lines established by accurate measurements, to which all the other details are tied either by rectangular or polar coördinates or a combination of both. The simplest topographic survey is that for a railway location. A single survey line or centre line is established on the ground by stakes driven at 100-foot intervals. The direction of this line is determined by angular measurements with a transit, starting from a line of known direction. When it has been marked upon the ground by stakes as described, the line is leveled (see **LEVELING**) and the elevations of the ground at each stake determined. With the notes of the transit and level surveys the topographer follows over the line and locates the contours, or such contours as it is desirable to show, of a belt of country 250 to 500 feet on either side of the centre line. Contours are the traces of parallel horizontal planes on the surface of the ground, or what would be the shore line at successive stages if the ground were first submerged and the water allowed to recede in stages of 2, 3, 5, 10, 20, or 50 feet, whichever is chosen as the contour interval. The instruments ordinarily used by the railway topographer are a hand level and a cloth tape.

When topographic surveys are made of extensive areas, the foundation network is usually a system of triangulations established by precise or geodetic methods. The important features of the landscape are then tied into this network of known points by means of coördinates in both vertical and horizontal planes. Measurements in both planes are made by stadia "shots," taking into account the vertical angle from the plane of the horizon to the point sighted at. The stadia (q.v.) is the most simple instrument for measuring distances ever devised. It is the invention of James Watt, the English engineer, and was used by him in canal surveys in the last quarter of the eighteenth century.

A topographic survey may be made by stadia, using a transit and afterward plotting the notes of the survey in the office, or it may be made with a plane table (q.v.), in which case the computations are made and the map is plotted in the field while making the survey. The United States Geological Survey is engaged in making topographic surveys of the entire country. These surveys are based on the primary triangulation system established by the United States Coast and Geodetic Survey, which system is further subdivided into secondary and tertiary triangulation systems by the Geological Survey.

**Hydrographic Surveying.** Hydrographic surveying is a general term which includes two very different kinds of work. Charts of the sea-coast and the shores of any body of water are intended to show much the same information in

regard to the sea bottom that topographic maps show of the surface of the land. Depths of water are determined by sounding lines. The location of each sounding with respect to some known lines or points is determined in a variety of ways, based either on rectangular or polar coordinates. In recent years the United States Coast and Geodetic Survey has developed a method of verifying the depths of extensive areas or of determining shoals or obstructions in those areas by sweeping over them with long wire drags or sweeps, which consist essentially of a horizontal wire suspended at any desired depth and drawn through the water by small power boats. See HYDROGRAPHY.

The other kind of surveying included under the term "hydrographic" is the measurement of stream flow. There are several methods; the simplest, of course, is to measure the size of the stream bed and the velocity of the flow. Hydrographic surveying also includes studies of rainfall and run off and other allied subjects.

**Mine Surveying.** Mine surveys are of two classes: (1) surveys to determine the surface location and boundaries of mining claims; and (2) underground surveys to determine connections, lay out work, establish the relations of the underground workings to the surface lines, points, and so on, and measure the ore removed or still in the mine. The surface methods employed are substantially land surveying methods as modified by the local and general mining laws. The underground surveys comprise carrying surface locations underground, lining on the galleries and shafts, running levels, etc., and laying out tramways and railroads. This work is ordinarily carried on much the same as it is on the surface. See MINES AND MINING.

**City Surveying.** City surveying is ordinary land surveying in theory, but geodetic or precise surveying in practice. Linear measurements are accurately made with standardized steel or invar tapes, making allowance for the stretch and sag of the tape and its change in length from differences in temperature. Angular measurements are made to seconds of arc by repeating the measurement and averaging the sum of these repetitions. Land in great cities is often worth several thousand dollars a front foot, and errors of a fraction of an inch would be costly.

**Measurement of Earthwork.** The determination of earthwork quantities is one of the most important functions of the surveyor and civil engineer. It requires careful measurements in both horizontal and vertical planes. The horizontal measurements with tape and transits furnish the plan, as in any survey, and the vertical measurements with level and level rod furnish the cross sections. From these the volumes of the inclosed prisms of earthwork are computed. See COAST AND GEODETIC SURVEY; ENGINEERING, MILITARY; GEODESY; GEOLOGICAL SURVEY; SURVEYING INSTRUMENTS; LEVELING; PHOTOGRAPHIC SURVEYING; PLANE TABLE; STADIA.

**SURVEYING, MARINE.** See HYDROGRAPHY.

**SURVEYING INSTRUMENTS.** The various instruments used by the engineer and surveyor in determining elevations, directions, and distances in their work of mapping land and locating and laying out engineering works. They may be broadly divided into instruments for (1) measuring distances, (2) determining directions, (3) determining horizontal lines, (4) measuring angles, and (5) miscellaneous work.

For measuring distances chains, tapes, and wooden or metallic rods may be used. The chain is of two kinds, the Gunter and the engineer's. The former was invented by Edmund Gunter, an English engineer, in 1620 and is 66 feet long, divided into 100 links, each of which is 7.92 inches long. These links are composed of heavy steel wire and each includes one, two, or three rings of the same material. At every tenth link is a numbered brass tag, while at each end of the chain is a handle. This chain is used now only in connection with the United States Public Lands or farm surveys, where the unit of area is the acre, of which the Gunter chain is an integral part, and where extreme accuracy is not a required essential.

The engineer's chain is similar to the Gunter chain except for the fact that it is 100 feet long instead of 66 and has, as the other, 100 links each 1 foot long instead of 7.92 inches. It too is seldom used except in a rough reconnaissance or in the preliminary location of the centre line of a railroad, where the stations or marks are 100 feet apart, therefore a chain length, and where, in rough country, a tape is likely to be broken.

The tape is now universally used, as it is more convenient, less bulky, more accurate, reads to finer divisions, and is in every way superior to the chain. Tapes vary from the small 3-foot pocket tape to the 1000-foot tape used in mine surveys, and usually are thin ribbons of steel or a nickel-steel alloy with small temperature coefficient known as invar (q.v.) with the feet and subdivisions etched upon them, though there are cloth and metallic tapes which are made of oiled cloth, the latter with threads of metal woven into them to prevent stretching. The usual length is 50 or 100 feet.

In very precise surveying, i.e., in geodetic work, metallic rods or bars called base bars are used to measure the base lines, upon which a system of triangulation is built up for the purpose of accurately locating points and determining distances. The United States Coast and Geodetic Survey makes use of invar tapes carefully standardized and with care paid to support, tension, and conditions of temperature. See GEODESY.

For measuring direction the most simple instrument employed is the surveyor's compass, but it is now rarely seen. This consists essentially of two uprights having vertical slits to

give a line of sight, which are attached to a horizontal graduated circle at the centre of which is mounted a magnetic needle free to move, the whole being supported with devices for leveling. The use of the needle compass is confined almost entirely to land surveying when extreme accuracy is not of great importance. It is used by setting up the instrument over one point of the line whose direction is to be determined, and sighting through the upright slits at a mark or rod set at another point of the line, and then by means of a graduated plate reading off the deviation of this line of sight from the north and south line indicated by the needle. The solar compass was a modification of the above, but from an observation on the sun the true meridian and the bearing of a line are determined instead of the magnetic bearing. The prismatic compass is a hand instrument with a glass prism so arranged that the needle is read while taking the sight.

For determining horizontal lines the engineer's level is the instrument most commonly employed. This instrument consists of a telescope with cross hoist to determine the line of sight, clamped in Y-shaped uprights rising from a bar and carrying a spirit level and resting on a vertical pivot revolving in a socket in the plate which fastens the instrument to its tripod or other support. Leveling screws permit the adjustment of the spirit-level bar to a horizontal position, and, when the axis to the telescope is parallel to this bar, the line of sight is horizontal. In connection with the level there is used a level rod graduated to feet and fractions of feet and having a target which can be slid up and down the rod to coincide with the line of sight through the telescope. The form of level just described is often called a Y level. A dumpy level has a short telescope with a wide aperture. An architect's level has a compass attachment. The level is used to find the relative elevation of points a considerable distance apart, to obtain the profile of a line, and to establish a grade. See LEVELING.

For measuring angles the instrument most commonly used by engineers is the transit. This is the most useful and universal of surveying instruments. Besides measuring horizontal and vertical angles it will read distances by means of stadia wires, determine bearings by means of the magnetic needle, do leveling by means of a bubble glass attached to the telescope, and do the work of a solar compass by means of a special device attached for the purpose. The transit consists essentially of two concentric circular plates of copper, brass, or other material (the upper plate or upper horizontal either being smaller and let into the lower or lower horizontal, or the rim of the lower raised round the outside of the upper) moving round a common axis, which, being double, admits of one plate moving independently of the other. Upon the upper horizontal rise two supports, bearing a horizontal crossbar, which is the axis of a vertical circle. This circle either has a telescope fixed concentric with itself, or a semicircle is substituted for the circle, and the telescope is laid above and parallel to its diameter. The circles, as their names denote, are employed in the measurement of horizontal and vertical angles. For these purposes the outer of the horizontal circles is graduated, and the inner carries the index point and the verniers (q.v.); the vertical circle is also graduated, and the graduations are generally read off by an index point and vernier firmly attached to

the supports. The upper horizontal is furnished with two levels placed at right angles to each other for purposes of adjustment and has a compass box let into it at its centre. The stand consists of a circular plate supported on three legs and connected with the lower horizontal by means of a ball-and-socket joint, the horizontal adjustment of the instrument being effected by means of three or four (the latter number is the better) upright screws placed at equal distances between the plates. The telescope is so fixed as to be reversible, and the adjustments are in great part similar to those of other telescopic instruments, but are too numerous and minute to be detailed here. Both horizontal plates being made, by means of the screws and levels, truly level, the telescope is pointed at one object, and the readings off from the graduated circle again performed; and by the difference of the readings the angular horizontal deviation is given. When vertical angles are required, the readings are taken from a vertical circle in a similar manner.

An instrument of the same construction, but the telescope of which cannot make a complete revolution on the horizontal axis, and thus does not transit, is usually called a theodolite. Theodolites are commonly made larger and more powerful than transits and are mostly used in important triangulation work for coast and geodetic surveys, etc. (See illustration under GEODESY.) The sextant (q.v.) is a convenient hand instrument for measuring angles universally and for making observations on shipboard, and also frequently used by engineers in surveying when angles have to be measured from a boat, as in locating soundings, buoys, etc. The plane table (q.v.) is an instrument for making topographic surveys and consists of an ordinary drafting board mounted on a tripod together with an instrument called an alidade. This latter consists of a line of sight, usually telescopic, mounted on a vertical support to which is attached a ruler, the edge of which is parallel to the line of sight.

Among miscellaneous engineers' instruments may be mentioned the aneroid barometer (q.v.) for determining altitudes; the pedometer for recording the number of steps taken by a walking man, which number multiplied by the length of step gives the distance traveled; the odometer, cyclometer (qq.v.), or speedometer, which record the number of revolutions of a wheel, which number, multiplied by the circumference of the wheel, gives the distance traveled; the clinometer, a device for measuring the dip of a vein, etc.; the planimeter (q.v.), a device for measuring irregular areas which have been mapped to scale; the pantograph (q.v.), for reproducing to the same or different scales from maps drawn on paper; and various drawing instruments, used in making maps and scale drawings of structures and machines. The heliotrope is an instrument used in geodetic surveying for the purpose of locating for the observer the station he wishes to observe, and at the same time it acts as the object to be sighted. It consists of one or more mirrors so arranged as to reflect a ray of light to the observer. See GEODESY; PHOTOGRAPHIC SURVEYING; SURVEYING. Consult: I. O. Baker, *Engineers' Surveying Instruments* (2d ed., New York, 1892); A. T. Walmisley, *Fieldworks and Instruments* (ib., 1904); J. B. Johnson, *Theory and Practice of Surveying* (17th ed., ib., 1910); W. F. Stanley, *Surveying and Leveling Instruments* (4th ed., ib., 1914).

**SURVEYS, MILITARY.** See **ENGINEERING, MILITARY.**

**SURVEYS, NATIONAL.** See **COAST AND GEODETIC SURVEY, UNITED STATES; GEOLOGICAL SURVEY, UNITED STATES.**

**SURVIVORSHIP.** A term commonly employed to describe a doctrine prevailing in some jurisdictions to the effect that where two or more persons perish in the same accident or calamity there is a presumption of law that the stronger of them survived the others. This doctrine originated in the Roman and civil law, but generally no presumption exists in England or most of the United States, and a person seeking to establish the survivorship of one who lost his life with others in the same peril must do so by logical and relevant evidence as in any other case, or he will fail to sustain the burden of proof resting upon him. This proof need not be direct; the facts and circumstances may be shown if they furnish any reasonable basis for a conclusion. See **EVIDENCE; PRESUMPTION.**

**SURVIVORSHIP, RIGHT OF.** The right of a person holding a title jointly with another to succeed to the latter's rights upon his death, by operation of law. This right exists in case of joint tenancies, in the absence of statutes to the contrary; in a husband and wife where they hold real property as tenants by the entirety; and in surviving partners after the death of another for the purpose of winding up the business, and in some forms (tontine) of life insurance. See **INSURANCE; JOINT TENANCY; PARTNERSHIP; PROPERTY.**

**SURYA, sūr'yā** (Skt., sun). In Hindu mythology, the god of the sun, who is honored in the hymns of the Rig-Veda. (See **VEDA.**) All creatures depend on him, for he drives away disease and upholds the sky. His father is variously said to be Dyaus, the sky, or Indra (q.v.), or Soma (q.v.). On the other hand he is the son of Aditi or of Ushas (q.v.), who is also regarded in other hymns as his wife, who bears the Asvins (q.v.). In later mythology Surya is the son of the sage Kasyapa and Aditi. He married Sanjna, who, overpowered by his radiance, left him, substituting for herself Chaya (Shadow). When he discovered this, he prevailed on his wife to return, and at his request his father-in-law, Tvastar, the divine craftsman, ground off one-eighth of his brightness, from which were made the disk of Vishnu (q.v.), the trident of Siva (q.v.), and other divine implements. He is still worshiped on the first Sunday of the month of Magha (January-February), although he has degenerated into a petty godling in modern times. Consult: A. A. Macdonell, *Vedic Mythology* (Strassburg, 1897); W. J. Wilkins, *Hindu Mythology: Vedic and Puranic* (2d ed., London, 1900); Maurice Bloomfield, *Religion of the Veda* (New York, 1908); L. D. Barnett, *Antiquities of India* (ib., 1913).

**SURYASIDDHANTA, sūr'yā-sēd-hān'tā** (Skt., textbook of the sun). The earliest Hindu astronomy that has been preserved, composed after c.300 A.D. It was one of four treatises and is written in verse containing 14 chapters. For the adherents of the Hindu science of astronomy it yet remains the chief authority in India, along with the work of Brahmagupta (q.v.). It is probable that Greek astronomy exercised some influence over this as over later Hindu works on this science. The *Suryasiddhanta* has been published repeatedly in India, the best editions being those by Hall and Deva Sastri (Cal-

cutta, 1859) and Dvivedi (ib., 1911). It has been translated into English by Deva Sastri (ib., 1860) and by Burgess and Whitney in the *Journal of the American Oriental Society*, vol. vi (New Haven, 1860). Consult Thibaut, *Astronomie, Astrologie und Mathematik* (Strassburg, 1899), and L. D. Barnett, *Antiquities of India* (London, 1913).

**SUS'A** (Lat., from Gk. Σούσα, *Sousa*, Heb. *Shūshan*, Pers. *Shūs*). The capital of the Province of Susiana or Elam (q.v.) in Persia and a very important city of the ancient East. The site is in a plain in the modern Province of Khuzistan between the Ab i Kerkhah (the ancient Choaspes) and the Shaur (the ancient Eulæus) (Map: Persia, C 5). It is marked by the so-called tomb of Daniel, a pilgrimage shrine of repute, and by the Kaleb i Shus (acropolis of Susa), with extensive ruins that consist of three spacious artificial platforms more than 100 feet high. The name of Susa occurs on Assyrian monuments of the time of Asurbanipal (668-625 B.C.), who captured it in 645 B.C. (See **ASSYRIA; SARDANAPALUS.**) At first under Babylonian dominion, it came, at the time of Cyrus (q.v.), under Persian rule, and the Achaemenian kings raised it to the dignity of a metropolis of the Persian Empire. (See **ACHÆMENES.**) When Babylon had risen again to importance under Alexander and his successors, Susa gradually declined. In the Arab conquest of Persia it held out bravely for a long time, defended by Hormuzan. During the Middle Ages it was still inhabited and known for its manufactures of sugar. Excavations by Williams, Loftus, Dieulafoy, and others have revealed a citadel of semicircular form and the remains of the extensive colonnade, with a frontage of 343 feet and a depth of 244 feet, of the great palace built by Darius Hystaspis (q.v.) and restored by Artaxerxes Mnemon (q.v.), after having been ruined by fire in the reign of Artaxerxes Longimanus (q.v.). Cuneiform inscriptions, friezes of lions and archers, finely colored, now in the Louvre at Paris, and other remains have been recovered. Consult: Dieulafoy, *L'Acropole de Suse* (3 parts, Paris, 1888-92); Billerbeck, *Susa* (Leipzig, 1893); J. de Morgan, *Fouilles à Suse* (Paris, 1900); L. de Milloué, "Les fouilles de Suse," in the *Annales du Musée Guimet*, vol. xxvi (ib., 1907).

**SUSA, sūz'à** (Lat. *Segusio*). An episcopal city in the Province of Turin, Italy, 32 miles by rail west of the city of Turin, on the Dora Riparia (Map: Italy, A 2). It has a triumphal arch 44 feet high, dedicated, the inscription reads, in 8 A.D. to Augustus. Its cathedral dates from 1020. It was formerly of strategic importance, being regarded as the key to the Alpine roads over Mont Cenis and Mont Genève. Pop. (commune), 1901, 4957; 1911, 3874.

**SUSA, or SOUSSE.** A port of Tunis, on the Gulf of Hammamet, in the Mediterranean Sea, 32 miles east-northeast of Kairwan, with which it is connected by rail, as also with Tunis (Map: Africa, F 1). It is surrounded by old walls, and its lofty, ancient, and restored citadel is used as the French military headquarters. A large modern town has grown up north of the old port, whose harbor, constructed in 1901, allows vessels of 25 feet draft to approach the quays. Phosphates, oil, cereals, and esparto grass are the chief exports. Susa is on the site of the Roman city of Hadrumetum. Pop., about 27,000, including some 6000 Europeans.

**SUSAN'NA** (Gk. Σούσanna, *Sousanna*, from

Heb. *shūshan*, lily), HISTORY OF, also known as THE JUDGMENT OF DANIEL and as SUSANNA AND THE ELDERS. One of three deuterocanonical additions to the Book of Daniel in the Greek Bible, the others being *The Song of the Three Holy Children* and *The History of Bel and the Dragon* (q.v.). The story of Susanna is as follows: in the early days of the Babylonian captivity there lived a woman, Susanna by name, who was celebrated for her beauty and her virtue. She was the wife of Joiachim, a wealthy and respected man, and daughter of a priest, Hilkiah. Two elders, who were also judges and held in high repute, were seized by desire for Susanna and, meeting each other unexpectedly in Joiachim's garden, agreed to coerce her. Susanna refused to listen to them, and in revenge the elders accused her of adulterous relations with a young man who had fled when surprised by their sudden appearance. She was condemned to death on this evidence, but Daniel, then a very young man, appeared and undertook to prove Susanna's innocence. By questioning the witnesses apart and showing discrepancies in their testimony he succeeded. The people applauded Daniel and put Susanna's accusers to death. It was probably written originally in Aramaic or Hebrew. Kay assumes a date of c.136 B.C., but it may be earlier. In most manuscripts it precedes the first chapter of the Book of Daniel, and so we find it in the old Latin and Arabic versions; but the Septuagint, the Vulgate, the Complutensian Polyglot, and the Hexaplar Syriac place it at the end of the book and reckon it as the thirteenth chapter. Consult: Fritzsche, *Apokryphen* (Leipzig, 1871); Otto Zöckler, *Apokryphen des Alten Testaments* (Munich, 1891); Emil Kautzsch, *Apokryphen und Pseudepigraphen des Alten Testaments* (Tübingen, 1899); D. M. Kay, in Charles, *The Apocrypha and Pseudepigrapha of the Old Testament* (Oxford, 1913).

**SUSANNES GEHEIMNISS**, zōō-zān'nēs gehim'nīs. See SEGRETO DI SUSANNA.

**SUSEMIHL**, zōō'ze-mēl, FRANZ (1826-1901). A German classical scholar, born at Laage in Mecklenburg-Schwerin. He was appointed professor of classical philology at the University of Greifswald in 1856. Among his works the most valuable are: *Die genetische Entwicklung der Platonischen Philosophie* (1855-60); text editions of Aristotle's *Politics* (with Ger. trans., 1879) and *Ethica Nicomachea* (1880); the very important treatise, *Geschichte der griechischen Litteratur in der Alexandrinerzeit* (1891-92). Consult J. E. Sandys, *A History of Classical Scholarship*, vol. iii (Cambridge, 1908).

**SUSIAN**, sōō'si-an. See CUNEIFORM INSCRIPTIONS.

**SUSITNA**. See IDITAROD.

**SUSITNA VALLEY**. The main watershed of the Susitna River, the principal affluent of Cook Inlet, Alaska (Map: Alaska, J 5). It has an area of about 8000 square miles, is fairly timbered, and has sections suited for agriculture and stock raising. The Susitna route of the government railway between Cook Inlet and Fairbanks, Tanana valley (q.v.), runs from the head of Knik Arm westerly and northwesterly, crossing the Little Susitna, to Willow Creek; thence northerly, following the drainage of the Susitna and Chulitna rivers to Broad Pass into the Tanana valley.

**SUSO**, zōō'zō, or **SEUSE**, zoi'ze, HEINRICH (c.1295-1366). A German mystic. He was born at Ueberlingen, Baden. At the age of

13 he entered the Dominican Order and spent most of his life in monasteries at Constance and Ulm. He was impulsive and an enthusiastic disciple of Eckhart (q.v.), but gives the master's speculative ideas a spiritual expression. He was truly called "the sweet" Suso on account of his poetry and childlike religion. He was not a member of the Brethren of the Free Spirit, as has sometimes been supposed. His *Autobiography* and his *Book of Everlasting Wisdom* have been translated into many languages and are both of unique importance for the study of the psychology of mysticism. He died at Ulm and was beatified by Gregory XVI in 1831. Consult H. Diepenbrock, *Heinrich Suso: Leben und Schriften* (Regensburg, 1829, 1837, and Vienna, 1863; new ed. by H. E. Bihlmeyer, Stuttgart, 1907; Fr. trans. by Thiriot, Paris, 1899), and R. A. Vaughan, *Hours with the Mystics* (7th ed., London, 1895). A more critical edition of Suso's works is that by Denifle (Augsburg, 1878-80), and there is an English translation (London, 1865).

**SUSPENDED RAILWAY**. See MONORAIL.

**SUSPENSION**. See HARMONY, *Anticipations, Suspension, Resolution*.

**SUSPENSION BRIDGE**. See BRIDGE.

**SUSPENSOR** (from Lat. *suspendere*, to hang). A special, usually filamentous organ developed by and at the base of the embryo, which is thereby related more effectively to its food supply. The suspensor chiefly appears among seed plants. See EMBRYO.

**SUSQUEHANNA**, sūs'kvē-hān'ā. A borough in Susquehanna Co., Pa., 23 miles southeast of Binghamton, N. Y., on the Susquehanna River and on the Erie Railroad (Map: Pennsylvania, K 2). Shops of the railroad are here. The institutions include the Barnes Memorial Hospital, public library, and Y. M. C. A. There are manufacturing of metal goods and washing machines. Pop., 1900, 3813; 1910, 3478.

**SUSQUEHANNA RIVER**. A river draining the greater part of Pennsylvania (Map: Pennsylvania, J 5). It rises in Otsego Lake, central New York, and flows southward in three large zigzag bends across Pennsylvania and into Maryland, where it empties into the north end of Chesapeake Bay at Havre de Grace after a total course of about 500 miles. It is almost throughout a shallow, swift, and unnavigable stream, but its entire course is through some very populous industrial and mining regions. After flowing through the northern plateau it enters the anthracite districts of the Appalachian valley. First it follows one of the western longitudinal valleys, and then turning to the southeast it breaks through all the Appalachian ridges, after which it traverses the more open but still picturesque piedmont plain. It receives its chief tributaries from the west, the Chemung, which joins it near the New York boundary, the large West Branch, 200 miles long, and the Juniata. Its lower and middle course is followed by a lateral canal, but its only importance as a waterway is for floating lumber. The chief cities on its banks are Harrisburg and Wilkes-Barre in Pennsylvania, Port Deposit in Maryland, and Binghamton in New York. The principal city on the West Branch is Williamsport.

**SÜSS**, zūs, HANS, also called HANS VON KÜLMBACH (c.1476-1522). A German historical painter and engraver. He was born at Kulmbach in Franconia, studied at Nuremberg under

Jacopo dei Barbari, a Venetian, and later worked in Dürer's studio. In 1514 he went as court painter to Cracow, where 13 of his paintings are preserved, and in 1518 he returned to Nuremberg. The influence of both his masters can be traced in his works, that of the Venetian being most visible in the "Adoration of the Kings" (1511, Berlin Gallery), "St. George" (Germanic Museum, Nuremberg), and the "Blessing of the Chalice" (St. John's Chapel, Cracow); and that of Dürer in the "Last Supper" (ib.), eight scenes from the "Lives of St. Peter and St. Paul" (Uffizi Gallery, Florence), and his masterpiece, the "Coronation of the Virgin" (church of St. Sebaldus, Nuremberg). Süß was one of the most important of Dürer's followers. His color is pleasing, his light effects often beautiful, and his rendering of material fine, but his types are often superficial, and he lacked imagination and nobility of conception.

**SUSSEX.** A maritime county of southeast England (Map: England, F 6). Area, 1458 square miles. Pop., 1901, 605,052; 1911, 666,229. The South Downs traverse the county from west to east, ending about 20 miles east of Brighton, in the lofty cliff of Beachy Head, and the northern escarpment of the Downs leads down to the fertile and richly wooded district of the Weald. The chief rivers are the Arun, Adur, and Ouse. A remarkably productive tract of land extends west from Brighton along the coast to the Hampshire border, and in the south-east of the county the rich marsh lands that line the coast make excellent pasture grounds. The Down lands are covered with a fine, short, and delicate turf, on which the well-known breed of Southdown sheep are pastured. The principal industries of the county are agriculture and cattle raising. Thick beds of gypsum are worked at Netherfield. The fisheries are important, and there are large railway works at Brighton. Capital, Chichester. See *Victoria History of the County of Sussex*, vols. i, ii (London, 1905-07).

**SUSSMANN-HELLBORN**, zŭs'män hēl'-börn, LOUIS (1828-1908). A German sculptor, born in Berlin, where he studied under Wredow and where he settled in 1857 after a sojourn in Rome (1852-56). Of his genre and mythological subjects, a "Drunken Faun" (1856) and "Sleeping Beauty" are in the National Gallery. His monumental work is represented by statues of "Frederick the Great in Youth" (1862), City Hall, Breslau; "Frederick the Great in Mid-Age" and "Frederick William III" (both 1869), City Hall, Berlin; "Holbein" and "Peter Vischer," both in the Art-Industrial Museum, Berlin, which he helped to establish in 1867. Sussmann-Hellborn was artistic director of the Royal Porcelain Factory in 1882-87.

**SUSTERMANN**, sŭs'tēr-män. See LOMBARD, LAMBERT.

**SUTRIS**, sŭs'trīs. See LOMBARD, LAMBERT.

**SUTECH**, sŭt'ōk. An Egyptian deity. See SET.

**SUTHERLAND.** A county of north Scotland (Map: Scotland, D 1). Area, 2028 square miles. Pop., 1901, 21,440; 1911, 20,180, the majority of whom speak Gaelic. The coast line is 60 miles in extent, and the shores, rugged on the north and west, where they are broken by the force of the Atlantic, are comparatively flat on the east. The southern and central regions of Sutherland are the most elevated; the principal mountain peaks are Ben More in Assynt (3273 feet) and Ben Clibrigg (3154 feet). The

chief rivers are the Oikel and the Shin. Extensive moors stretch across the county, and the rivers and lakes, the chief of which is Loch Shin, form numerous low-lying valleys or straths. In the eastern districts the soil is very fertile, yielding all kinds of agricultural produce. Coal, granites of various colors, marble, limestone, etc., are found; there are good salmon, herring, and other fisheries. The capital is Dornoch.

**SUTHERLAND, ALEXANDER** (1833-1910). A Canadian Methodist clergyman. He was born in Wellington County, Ontario, early became a printer, and after attending Victoria College, Cobourg, was ordained to the Wesleyan Methodist ministry in 1859. Subsequently he was pastor of important churches in Hamilton, Toronto, and Montreal. He was elected missionary secretary of his church in 1874 and displayed remarkable zeal and eloquence as well as business ability in expanding and consolidating the missionary interests committed to his charge. An active worker in the temperance cause, he was made president of the Prohibition Third party in Ontario. He took a foremost part in the work of uniting the Wesleyan Methodist, Methodist Episcopal, Bible Christian, New Connexion, and Primitive Methodist denominations into one Methodist church in 1883.

**SUTHERLAND, GEORGE** (1862- ). An American lawyer and legislator, born at Stony Stratford, Buckinghamshire, England. His parents brought him to the United States in 1864 and settled in Utah. He graduated from Brigham Young University in 1881 and, in law, from the University of Michigan in 1883. After 1893 he practiced law in Salt Lake City. A staunch Republican, he was a member of the Utah Senate (1896-1900), a Representative in Congress (1901-03), and Senator (1905-11; 1911-17). He was regarded as one of the ablest lawyers in the Senate and was frequently mentioned for the Supreme Court, but gained the reputation of an ultraconservative in politics. Sutherland showed deep interest in irrigation problems and in the conduct of foreign relations. He was a delegate to several Republican national conventions. In 1913 Columbia University gave him the degree of LL.D.

**SUTLEJ**, or **SATLEJ**. The chief tributary of the Indus. It rises in the southern part of Tibet near the sources of the Indus and the Brahmaputra, and, after winding through the Himalaya past Simla, it flows southwest through the great arid plains of the Punjab, joining the Indus in the southwestern part of that province after a course of about 950 miles (Map: India, B 3). After passing through Lake Manasarowar (q.v.) the river, whose upper course is very rapid, flows through a series of lofty and highly picturesque mountain valleys. In the low doabs of the Punjab its waters are largely used for irrigation, but its volume is nevertheless almost equal to that of the Indus. The Sutlej is the eastern and southernmost of the Five Rivers of the Punjab, the other four being its two main tributaries, the Beas and the Chenab, together with two branches of the latter. Below the confluence of the Beas the river is sometimes called the Ghara, and its lowest course, after receiving the Chenab, is called the Panjnad, or Five Rivers.

**SUTRA**, sŭt'rā (Skt. *sūtra*, thread, clew). In Sanskrit literature, the technical name of brief, aphoristic rules and works consisting of such

rules. The object of the sutras is to supply a short survey of the facts of any given science in a form so brief that the whole theme may be memorized. In the later works of this class brevity and allusiveness are carried to such an excess that, but for the aid of commentaries which regularly accompany them, they would be obscure and sometimes absolutely unintelligible. Probably this peculiar style of writing originated with the mnemonic methods of teaching which have prevailed in India from early times.

The importance of the sutras will be understood from the fact that they form in very early times the standard medium of most of the ritual, legal, grammatical, metrical, and philosophical literature. The ritual sutras, known as *Srauta Sūtras* and *Grhya Sūtras*, are systematic compendiums of the priestly sacrifices and the ceremonies of the householder respectively. The *Dharma Sūtras*, the oldest sources of Indian law, are also rooted in the Veda (q.v.). There is another class of Vedic sutras, concerned with religious practice, the *Sulva Sūtras*, of which class the last chapter of the sutra collection of the school of Apastamba (q.v.) is an example. These are practical manuals giving the measurements of the altars, etc. They show quite an advanced knowledge of geometry and constitute the oldest Indian mathematical works. In addition the systematic study of the Vedas produced a series of ancillary Vedic sciences in sutra style, the so-called six Vedangas (q.v.). The most important class of these texts are the *Prātiśākhya Sūtras*, which deal with accentuation, pronunciation, and other matters, but are chiefly concerned with the phonetic changes undergone by Vedic words when combined in a sentence. Their observations are so minute and acute as to approach the best results of the modern science of phonetics. A still more important branch of sutra literature is grammar, in which the Hindus again surpass all nations of antiquity. The systematic analysis of words into roots, suffixes, and inflectional elements evolved by Panini (q.v.) has been adopted with unimportant changes by modern grammarians.

Later systematic philosophy, which has grown up on the basis of the theosophic hymns of the Veda and the Upanishads (q.v.), also adopts the sutra style of presentation in the six systems of philosophy. Even so remote a theme as erotics is given in the *Kāmasūtra* (Love Sutra) of Vatsyayana, who naïvely treats this subject in the form of sutra rules. In one quarter, however, the sutra has abandoned its style and has become the reverse of brief, for the Buddhist *Sūtras*, or *Suttas* (see PITAKA), the sermons ascribed to Buddha, excel in prolixity almost every other type of literature in existence.

**Bibliography.** A good bibliography of sutra texts that have been edited and published may be found in A. A. Macdonell, *History of Sanskrit Literature* (London, 1913). Among recent editions not mentioned in this work are *The Srauta Sūtra of Apastamba* (ed. by R. Garbe, 3 vols., Calcutta, 1901-03); *The Srauta-sūtra of Drāhyāyana* (ed. by P. N. Reuter, London, 1904); *Prayogādīpikā of the Aśvalāyana Srauta Sūtra* (ed. by Nyayopadhyaya and Kavyatīrtha, Benares, 1907); *Der Arşeyakalpa des Śāmaveda* (ed. by W. Caland, Leipzig, 1908); *Das Vaitānasūtra des Atharvaveda* (Ger. trans. by W. Caland, Amsterdam, 1910); *Sūtras of the School of Hiranyakeśin* (ed. by Okapahra, Poona, 1908-16). Consult also V. Henry, *Les littératures de*

*Vinde* (Paris, 1904), and E. J. Rapson, *Ancient India* (Cambridge, 1914).

**SUTRI**, sū'trē (anciently **SUTRIUM**). A town in the Province of Rome, Italy, 29 miles northwest of Rome. It is interesting for its ancient walls and gates, its Etruscan tombs, and the ruins of an amphitheatre dating from the time of Augustus. Sutri is known as the scene of the synod which in 1046 deposed Popes Gregory VI and Sylvester III. Pop. (commune), 1901, 2795; 1911, 2942.

**SUTRO**, sū'trō, ADOLPH HEINRICH JOSEPH (1830-97). An American mining engineer and philanthropist. He was born at Aix-la-Chapelle in Rhenish Prussia, came to the United States in 1850, and soon after went to the Pacific coast. He was best known as the designer and constructor of the famous Sutro Tunnel, built to drain and ventilate the mines of the celebrated Comstock silver lode in Nevada. It is 20,500 feet long and cost about \$6,500,000. It did not prove so valuable as had been hoped, but by investing the returns which he got from it in San Francisco real estate Sutro became a millionaire. In 1894 he was elected mayor of the city by the Populists. During his life he made numerous gifts to the city, and by his will left to it a park and a library of 250,000 volumes; but after his death the estate was involved in family lawsuits, and the library was packed away in storage, unclassified. In the earthquake and fire of 1906 about 150,000 volumes were destroyed. In 1913 a settlement was made by which Sutro's heirs gave to the State Library the books saved (about 100,000), on condition that they be kept in San Francisco.

**SUTTEE**, sūt-tē' (from Skt. *sati*, true wife). The practice which prevailed in India of a wife burning herself on the funeral pile, either with the body of her husband, or separately if he died at a distance. Suttee for the orthodox Hindus is based on the injunctions of their sacred books, and there can be no doubt that various passages in the Puranas (q.v.) and codes of law countenance belief in its efficacy. These, however, are all rather late texts. Classical authors mention it as early as 316 B.C. It has been referred to the Rig-Veda as authority, and it was even thought that a Vedic verse had been falsified to give support to the practice. This view, however, is untenable, for the Rig-Veda does not recognize the custom. Manu (q.v.), the lawgiver, does not sanction it either, though it was known before his time. It appears at first to have been a royal custom and privilege, afterward generalized and made legal. The custom was abolished by the British in 1829. Nevertheless it has continued to the present time in isolated parts of India, for even as late as 1905 several persons who took part in a suttee in Behar were condemned to penal servitude. Suttee is by no means confined to India. Under other names the widow's death at the grave of her husband is known in many parts of the world, notably in the South Pacific, where a king's favorite wives were wont to let themselves be buried alive in his grave. Consult: H. H. Wilson, *Collected Works*, vol. ii (ed. by Rost, London, 1862); H. T. Colebrook, *Miscellaneous Essays*, vol. i (new ed., ib., 1873); J. C. Bose, *The Hindus as they Are* (2d ed., ib., 1884); Jolly, "Recht und Sitte," in Bühler's *Grundriss der indoarischen Philologie* (Strassburg, 1896); E. B. Tylor, *Primitive Culture* (4th ed., 2 vols., New York, 1903).

**SUTTER, JOHN AUGUSTUS** (1803-80). An American pioneer, born in Kandern, Baden. He was of Swiss parentage and was educated at the military college at Bern. He emigrated to America in 1834 and became a trader at Santa Fe, N. Mex. In 1838 he made his way to the Pacific coast, thence to the Sandwich Islands, and finally to Alaska. Obtaining a grant of Mexican land, he established in 1841 a settlement called New Helvetia (Sutter's Fort), where the city of Sacramento now stands. He was Governor of the north district of California under the Mexicans, and alcalde and Indian agent after it passed to the United States. In February, 1848, gold was discovered on his estate. The discovery, however, brought him nothing but disaster. Gold diggers preempted his lands, and except an annual pension of \$3000 granted him by the California Legislature he received nothing. He settled in Pennsylvania in 1873. Consult F. S. Dellenbaugh, *Frémont and '49* (2d ed., New York, 1914).

**SUTTNER, zut'nēr, BERTHA BARONESS VON** (1843-1914). An Austrian novelist, especially known for her efforts to promote peace. Born at Pragü, the daughter of Count Franz Kinsky, she married, in 1876, Baron Arthur von Suttner (1850-1902), also known as a novelist. In 1891 she founded the Austrian Society of Peace Lovers and, as its president, took a prominent part in the peace congresses at Rome (1891), Bern (1892), Antwerp (1894), and Hamburg (1897). She edited *Die Waffen nieder!* (Dresden, 1892 et seq.), organ of the Peace Bureau at Bern, and in 1905 received the Nobel peace prize. Her novels include: *High Life* (1884; 3d ed., 1902); *Erzählte Lustspiele* (1889); *Die Waffen nieder!* (1889; 38th ed., 1907; translated into many languages; in Eng., *Lay Down Your Arms!*, 1905) and its sequel *Marthas Kinder* (1902); *Babiss siebente Liebe* (1905). She also wrote: *Das Maschinenzeitalter* (3d ed., 1898); *Die Haager Friedenskonferenz, Tagebuchblätter* (1900); *Der Krieg und seine Bekämpfung* (1904); *Randglossen zur Zeitgeschichte* (1906); *Stimmen und Gestalten* (1907); *Menschheit, Hochgedanken* (1912). A collected edition of her works appeared in 12 volumes (Dresden, 1906-07). Her *Memoiren* (1909) were translated as *Memoirs of Bertha von Suttner* (2 vols., Boston, 1910).

**SUTTON.** A town in Surrey, England, 11 miles south of London and a favorite residential district for London business men. Pop., 1901, 17,224; 1911, 21,270.

**SUTTON.** A town in Worcester Co., Mass., 9 miles south of Worcester, on the New York, New Haven, and Hartford Railroad (Map: Massachusetts, D 4). There are manufactories of cotton goods, shuttles, and ducking. Pop., 1900, 3328; 1910, 3078; 1915 (State census), 2820.

**SUTTON COLD-FIELD.** A municipal borough in Warwickshire, England, 7 miles north-northeast of Birmingham, of which it is a residential suburb (Map: England, E 4). The chief objects of interest are an ancient Early English church, the grammar school founded in 1543, and the celebrated Sutton Park, a recreation ground of 3500 acres, these two latter institutions due to the beneficence of Bishop Vesey of Henry VIII's reign, who also bequeathed real estate the annual revenue of which is applied to educational and charitable purposes. Pop., 1901, 14,264; 1911, 20,132.

**SUTTON IN ASH-FIELD.** A town in Nottinghamshire, England, 3 miles southwest of Mansfield, known for its hosiery manufactures. It has a church of the twelfth century. Pop., 1901, 14,862; 1911, 21,708.

**SU TUNG-P'O, or SOO TUNG-P'O, sū-tūng'p'o' (1030-1101).** The name by which Su Shih, a Chinese statesman and poet, is best known. He entered public service in 1060 and soon attracted the attention of the Emperor. At his own request he was appointed Governor of Hangchow (q.v.). He opposed the reforms of Wang An-shih, then in favor at the court, and was degraded in consequence and banished. On the death of the Emperor in 1086 he was recalled to the capital, where he filled several high posts, becoming president of the Board of Rites in 1091. The sarcasm of his verse, however, continued to make him enemies, and, being accused of speaking ill of the Emperor, he was again banished. A new Emperor having come to the throne, he was recalled in 1101 and restored to honor, but died soon after at Changchow in Kiangsu. In the estimation of the Chinese, Su stands in the first rank as a poet. An edition of his works in 115 books was issued in his lifetime, and there have been many since then with commentaries and new arrangements. Copious translated extracts are to be found in Giles, *Gems of Chinese Literature* (London, 1884), and his *Chinese Literature* (New York, 1901).

**SUTURE** (from Lat. *sutura*, seam, from *suere*, to sew; connected with AS. *siuran*, Eng. *sew*). A term employed both in anatomy and surgery. In anatomy it is used to designate the modes of connection between the various bones of the cranium and face. A suture is said to be serrated when formed by the union of two edges of bone with projections and indentations (like the edge of a saw) fitting into one another. The coronal, sagittal, and lambdoidal sutures (see SKULL) are of this kind. A suture is termed squamous when formed by the overlapping of the beveled (or scalelike) edges of two contiguous bones. There are also the harmonia and schindylesis sutures, the former being the simple apposition of rough bony surfaces, the latter the reception of one bone into a fissure of another. See JOINT.

In surgery the word is employed to designate various modes of sewing up wounds. The term is also applied to a single stitch. Two main varieties of suture are recognized, the continuous and the interrupted suture, and from these two a number of modifications have been made, of which the quill suture, button suture, glover's suture, quilt suture, and the intestinal sutures of Lembert and Dupuytren are examples. A buried suture is one which unites some deeper structure, such as a muscle or a layer of fascia, and which does not appear above the skin. It is often made of some absorbable material. Many materials are at present employed for sutures, such as silk, catgut, silk-worm gut, horsehair, kangaroo tendon, and silver wire. Consult J. C. DaCosta, *Modern Surgery* (7th ed., Philadelphia, 1914).

**SU'VA.** The capital and chief port of the British colony of the Fiji Islands (q.v.). It is situated on the south coast of Viti Levu, 1100 miles from Auckland and 1540 miles from Brisbane. There is good anchorage in a harbor accessible at all tides. There was in 1911 a European population of 1376.

**SUVAROV, sū-vā'róf, or SUVOROV, ALEXEI**

VASSILEVITCH, COUNT (1729-1800). A Russian field marshal. He was of Swedish descent and was born in Finland. He served in the campaigns of the Seven Years' War and was made a colonel in 1762 after the battle of Kunersdorf (1759). His services in the Polish War (1768-72), in the war against the Turks (1773-74), in suppressing the uprising of Pugatchev, and in subduing the Tatars of the Kuban (1783) gave him increased reputation, and he rose to the rank of general. In the Turkish War of 1787-92 he was commander in chief, first bringing the bayonet into use in the Russian army, and decided by it the battle of Kinburn (1787). At the siege of Otchakov (1788), the battle of Fokshany (1789), which he gained in conjunction with the Austrians, and the decisive victory of Rymnik (1789), his system of rapid and repeated attack by overwhelming numbers secured him success. For this last, which saved the Austrians under the Prince of Saxo-Coburg from annihilation, Suvarov was created by Emperor Joseph II a count of the Empire, and from his own sovereign received the title of Count Suvarov-Rymnikski. One of his great successes was the storming, in 1790, of the fortress of Ismail, where the whole Turkish garrison was killed. He was appointed (1791) Governor of the newly conquered provinces. In 1794 he was sent into Poland, where he completed the annihilation of the Polish monarchy by a victory won with Persen over the army of Kosciuszko, the capture of Praga, where a massacre of the inhabitants took place, and the occupation of Warsaw. The grade of field marshal rewarded these successes. Under Paul I he fell into disgrace (1798) because of his impatience with the Emperor's fantastic military regulations and was deprived of his rank, but, being restored through English influence, he commanded the army sent to cooperate with the Austrians in Italy against the French. He reached Verona in April, 1799; compelled Moreau to retire behind the Adda after defeating him at Cassano (April 27); entered Milan (April 29); again defeated the French under Macdonald at the Trebbia (June 17-19), and a third time under Joubert at Novi (August 15), driving them out of the whole of northern Italy. He next entered Switzerland in order to join Korsakov and effected a toilsome march across the St. Gotthard, in the course of which he lost one-third of his army. But Masséna defeated the army of Korsakov at Zurich (September 25), and Suvarov was compelled to execute a retreat through the Grisons and Vorarlberg. For these remarkable services he received the title of Prince Italiski. In 1800 he was named commander in chief of the Russian armies and ordered home. He arrived in the capital, where he died May 18, 1800. A monument was erected in his honor in 1801 at St. Petersburg. He left an autobiography in French, which was edited by Glinka (Moscow, 1819). Consult also: Friedrich von Smitt, *Suworows Leben und Heerzüge* (Vilna, 1833-34); id., *Suworow und Polens Untergang* (Leipzig, 1858-59); E. N. Macready, *A Sketch of Suvarrow and his Last Campaign* (London, 1851); Reding-Biberegg, *Der Zug Suworows durch die Schweiz* (Zurich, 1869).

**SUVORIN**, sŭv-vŏ'rĭn, ALEXEI SERGEIEVITCH (1834-1912). A Russian journalist and publisher. He was born in the Government of Voronezh, Russia, and studied at the Voronezh-Mik-

hailovsky Cadet School. In 1866 he wrote a novel, *Everybody*, which was destroyed by the censors, and 10 years later founded the most important Russian daily, *Novoye Vremya*. In 1872 he began the publication of the famous *Suvorin Calendar* and in 1881 appeared his monthly *Istoricheskoy Vestnik*. Besides he published several reference works and "Libraries" of Russian and foreign classics in hundreds of volumes. Suvarin actively promoted the Moscow Little Theatre and wrote plays for it, some of which (*Riepin's Tatiana*, a comedy, and *Media*, a tragedy) were very popular.

**SUWALKI**, sŭv-väl'kê. A government of Russian Poland situated in the northeastern part (Map: Russia, B 4). Area, 4763 square miles. The surface is generally flat and interspersed with lakes. The principal river is the Niemen. The soil is mostly fertile. About one-fourth of the area is in forests, which belong chiefly to the state and are extensively exploited. The principal occupation is agriculture. Pop., 1912, 693,000, half of whom were Lithuanians.

**SUWALKI**. The capital of the government of that name in Russian Poland, situated on a small tributary of the Niemen, 606 miles southwest of St. Petersburg (Map: Russia, B 4). Pop., 1910, 32,962. It was captured by the Germans in 1915. See WAR IN EUROPE.

**SUWANEE** (sŭ-wā'nê) **RIVER**. A river of Florida (Map: Florida, C, D 2). It rises in the Okefinokee Swamp in south Georgia and flows southwest, emptying into the Gulf of Mexico, 12 miles north of Cedar Keys, after a course of 240 miles. The scenery along its banks is attractive, and the river has been celebrated throughout the country by the song, *Old Folks at Home*.

**SUWARRO**, sŭv-wär'rŏ. See CEREUS.

**SUYEMATSU**, sŭv'yê-măt'sŭ, KENCHO, VIS-COUNT (1855- ). A Japanese statesman, son-in-law of Marquis Hirobumi Ito (q.v.). He was born in Fukuoka ken and in 1877 was civilian staff officer to the commander in chief of the army during the Satsuma Rebellion. He began his public life as a writer on the staff of the *Nichi Nichi* and later was attached to the Japanese Legation in London, of which he was appointed chancellor. He was a member of the Japanese House of Commons (1890-95), director of the Legislative Bureau (1892-95), Minister of Communications in the Ito cabinet (1898), Minister of the Interior in the Seiyukai cabinet (1900-01), and nonofficial agent in England during the Russo-Japanese War (1904-05). He was created Baron in 1895 for distinguished service in the Chinese War and Viscount in 1907. He made an English translation of *Genji Monogatari* and of Anderson's *Pictorial Japan* and published *The Risen Sun: A Fantasy of Far Japan* (1905).

**SUYUTI**, sŭv-yŭŭ'tê (Ar. *Ab'ul Faql 'Abd al Rahmân Jolel al din al Suyûti*) (1445-1505). An encyclopædist and the most prolific writer in Arabic literature. His family was of Persian origin, but had emigrated to Egypt, where his father was a judge and professor at Cairo. Hither the son returned after the usual travels to Mecca and the centres of learning, and here he rose from one professorship to another. But at last his arrogant and dishonest conduct drove him from his position, and he died in retirement. The production of great numbers of books seems to have been his affectation, and although they do not reveal genius, they are of value for the

encyclopædic information they contain. More than 500 titles of extant books of his are enumerated, touching upon every subject. Consult: Wüstenfeld, *Die Geschichtschreiber der Araber* (Göttingen, 1882); C. Brockelmann, *Geschichte der arabischen Literatur* (Berlin, 1899); R. A. Nicholson, *A Literary History of the Arabs* (New York, 1907).

**SUZZALLO**, sū'za-lō or sū'z'-lō, HENRY (1875- ). An American educator. He was born at San Jose, Cal., graduated in 1899 at Leland Stanford Junior University, where he was an instructor for several years, and in 1905 took his Ph.D. at Columbia, where he was adjunct professor of elementary education (1907-09) and professor of the philosophy of education (1909-15). In 1909 he was made editor of the *Riverside Educational Monographs*. In 1915 he accepted the presidency of the State University of Washington.

**SVANE**, svā'ně, or **SVANING**, svā'ning, HANS (1606-68). A Danish statesman and Lutheran churchman. He was born at Horsens and was educated at Copenhagen, Wittenberg, Leyden, Oxford, and Paris. In 1633 he became professor of Oriental languages, and in 1646 professor of theology, at the University of Copenhagen and in 1655 was made Bishop of Sealand. In the deliberations of the Rigsdag of 1660 Svane was chiefly responsible for the change from an elective monarchy to a hereditary and absolute monarchy. As a reward two special offices were created for him, that of Archbishop and that of president of the academic consistory of the university, neither of which offices have ever since been held by a Danish ecclesiastic. In addition he was made a royal counselor, a member of the Council of State, and an assessor of the Supreme Court.

**SVARGA**, swār'gū (Skt., heaven). In Hindu mythology, the paradise of the god Indra (q.v.). It is the residence of some of the inferior gods and deified mortals, who there rest in the shade of five wonderful trees, drink *amṛta*, the beverage of immortality, and enjoy the music of the heavenly musicians, the *Gandharvas*, and the dancing of the celestial courtesans, the *Apsarasas*. Svarga is situated on Mount Meru (q.v.) and is said to be 800 miles in circumference and 80 miles high. Its pillars are of diamonds and its palaces of gold. Consult A. A. Macdonell, *Vedic Mythology* (Strassburg, 1897).

**SVARTE HUK**, svūr'te huk. See **HEIBERG LAND**.

**SVEABORG**, svā'ā-bōr-y'. A fortress of Finland, Russia. See **HELSINGFORS**.

**SVEARIKE**, svā'ā-rē'ke. One of the three historical divisions of Sweden. It lies between Götarike and Norrland. Area, 32,539 square miles. Pop., 1900, 1,579,954; 1910, 1,735,192.

**SVENDBORG**, svēnd'bōra. A seaport of Denmark, on the southeast coast of the island of Fünen, on the Svendborg Sound, 27 miles south of Odense (Map: Denmark, D 3). The town occupies a charming site in a hill-encircled valley. The chief industries are iron founding, tanning, and shipbuilding. Pop., 1901, 11,531; 1911, 12,667.

**SVEND'SEN**, JOTAN (SEVERIN) (1840-1911). A Norwegian violinist and composer, born in Christiania. He studied at the Leipzig Conservatory (1863-67), toured extensively, later was appointed concert master of the Leipzig Enterpe concerts, and from 1872 to 1877 was conductor of the Christiania Musical Association. In 1883

he became court conductor at Copenhagen. He is one of the most important of Scandinavian masters, although his music shows few distinctly national characteristics. His works include string quartets and quintets; two symphonies, in D and B flat; violin concerto in A; overture to Björnson's drama *Sigurd Slembe*; *Carnaval à Paris*, for the orchestra; *Coronation March*, for Oscar II; *Wedding Cantata*, for chorus and orchestra; *Carnaval des artistes norvégiens*; a legend for orchestra, *Zorahayde*; Norwegian rhapsodies for the orchestra; overture to *Romeo and Juliet*; Scandinavian airs for string quartet; Romance in G, for the violin and orchestra.

**SVENGALI**, svēn-gā'li. A sinister character in George Du Maurier's (q.v.) novel, *Trilby*. He possessed hypnotic powers and through them transferred his musical knowledge to the heroine of that story, making her a great singer. His influence over her destroyed, she could no longer sing.

**SVERDRUP**, svēr'drup, GEORG (1770-1850). A Norwegian scholar and statesman, born in Namdalen. Educated at Christiania and Göttingen, he became professor of Greek at Copenhagen in 1803. He did much for the establishment of Christiania University, where for many years he was professor of Greek and Latin and later of philosophy. He was president of the Assembly at Eidsvold (May 17-19, 1814) which drafted the constitution of Norway. With C. M. Falsen, Sverdrup was the leader of the majority which offered to Prince Christian Frederik the crown of Norway. His services as member of the Storthings of 1818 and 1824 were also important.

**SVERDRUP**, JOHAN (1816-92). A Norwegian statesman, born at the château of Jarlsberg. He studied and practiced law, but from 1850, when he was elected to the Storting, gave his entire attention to politics and became the leader of the radical peasant party. As President of the Storting since 1871 he violently fought against the royal prerogatives. He was called to preside over the ministry in 1884, but did not satisfy the radical portion of his adherents and, yielding to the combined attacks of the Conservatives and the extreme Left, resigned in 1889. His work greatly furthered the development of popular government in Norway.

**SVERDRUP**, OTTO (1855- ). A Norwegian Arctic explorer, born at Harstad Farm, District of Helgeland. He followed the sea at the age of 17, was subsequently in command of a merchant vessel, and in 1888 joined Nansen's expedition to Greenland. In 1893 he started with Nansen for the North Pole as commander of the *Fram*, which had been built under his supervision, and when Nansen, in 1895, left the *Fram* in an attempt to reach the North Pole by dog sledge, Sverdrup, remaining with the ship, brought her safe to Norway through the ice of the following years.

He led another expedition in the *Fram* (1898-1902) in an unsuccessful attempt to circumnavigate Greenland. Unable to pass north of Cape Sabine, Smith Sound, he transferred his field of operations the second summer to Jones Sound, where his explorations and discoveries were notable in extent and in success. They include Heiberg and Ringnes lands, the most westerly coasts of Grinnell Land, and regions adjacent to Greely Fiord. When commanding an expedition for the relief of missing Arctic explorers, he wintered (1914-15) on the shores of Kara Sea. He

wrote *New Land: Four Years in the Arctic Regions* (1904).

**SVET'LA'**, KAROLINA. See MUŽÁKOVÁ, JOHANNA.

**SWABIA**, or **SUABIA** (Ger. *Schwaben*, Lat. *Suevia*). A mediæval duchy in the southwest of Germany. It took its name from the Suevi, by which the Germanic people of the Alemanni (q.v.), who occupied southwestern Germany in the third century, were also known. The name Suevia alternates with that of Alemannia as the designation of the country in the early part of the Middle Ages, but the former finally prevailed. The region occupied by the Alemanni embraced western Bavaria, Württemberg, Baden, Alsace, and a great part of Switzerland. The bulk of the nation was subjected by the Franks at the close of the fifth century. As part of the Frankish realm Alemannia was governed by native dukes, but the duchy was abolished before the dissolution of the Frankish Empire. The country from which Alsace and part of the Alpine territories had been detached, and which now came to be known as Swabia, was then placed under the rule of counts and *nuntii camerae*, and for a time it was nearly independent.

In 919 Swabia was constituted one of the great duchies of the German Kingdom. It comprised the region between the Rhine and the Lech and part of Switzerland. The office of duke was frequently kept in the royal family. In 1079 the duchy passed to the house of Hohenstaufen, being bestowed by the Emperor Henry IV upon Frederick of Staufen. In 1096 Frederick of Staufen was compelled to give up to Berthold of Zähringen the Breisgau and the Imperial bailiiffship in Zurich. Under the rule of the Hohenstaufens, who occupied the Imperial throne of Germany from 1138 to 1254, Swabia was the most wealthy and powerful of the German duchies. On the extinction of the Hohenstaufen dynasty in 1268 disintegration took place, and the ducal vassals (cities, prelates, counts, etc.) claimed independence except for their allegiance to the emperors. The Count of Württemberg occupied the leading place among the petty rulers. The numerous lesser lords were for the most part obliged to accept the overlordship of the house of Zähringen or of Austria. The cities, of which many had become wealthy and powerful, were striving for local independence. In 1331 some of them formed the first Swabian League. In 1405 Württemberg, Baden, and 17 cities joined together in the League of Marbach. The two leagues were of little importance as political powers, but they paved the way for the Great Swabian League, formed in 1488, which under the leadership of the Count of Württemberg exercised administrative and judicial authority over the whole country. During this long period of strife a considerable portion of old Swabia had passed into the power of Bavaria. In 1512 Swabia became one of the 10 circles into which Germany was divided for administrative purposes by Maximilian I. The dissolution of the Great Swabian League took place in 1534. Among the many city commonwealths which arose in Swabia were Augsburg, Ulm, and Constance (qq.v.). The southwestern Government District of Bavaria bears the name of Swabia (or Swabia and Newburg). Its capital is Augsburg. The best general history is P. F. Stälin, *Geschichte Württembergs* (Gotha, 1882-87). Consult also Eugene Schneider, *Württembergische Geschichte* (Stuttgart, 1896).

**SWABIA**, KONRADIN OF. See CONRADIN OF SWABIA.

**SWABIA**, PHILIP OF. See PHILIP OF SWABIA.

**SWADLINCOTE**, swōd'lin-kōt. A town in Derbyshire, England, 4 miles southeast of Burton-upon-Trent. Its industries comprise coal mining and the various branches of earthenware manufacture. Pop., 1901, 18,014; 1911, 18,674.

**SWAHILI**, swā-hē'lē. A Bantu people of the Kau District, Tana-Ozi Delta, British East Africa, mingled more or less in blood with Semites. They are Mohammedans and differ little from the Arabs in general culture. They number about 1,000,000. They are noted traders, and their language, the Kiswahili, is the great medium of intercourse throughout east Central Africa. Consult: Krapf, *Dictionary of the Swahili Language* (London, 1882); Büttner, *Wörterbuch der Suahelisprache* (Berlin, 1890); Seidel, *Grammatik der Suahelisprache* (Vienna, 1891); Steere, *Handbook of the Swahili Language* (4th ed., London, 1894); Madan, *English-Swahili Dictionary* (Oxford, 1894); Delaunay, *Grammaire Kiswahili* (Paris, 1898).

**SWAIN**, GEORGE FILLMORE (1857- ). An American civil engineer. He was born at San Francisco and was educated at the Massachusetts Institute of Technology, where he graduated in 1877. He then studied three years in the government engineering school at Berlin, Germany. Upon his return he settled in Boston, where he served as professor of civil engineering at the Institute of Technology from 1887 to 1909 and after 1887 as consulting engineer to the Massachusetts Railroad Commission. He was also made a member in 1894 and chairman in 1913 of the Boston Transit Commission. After 1909 he was professor of civil engineering at the Harvard Graduate School of Applied Science. Swain was president of the American Society of Civil Engineers in 1913. His most important publication is a "Report on the Water Power of the Atlantic Watershed" (vol. xvii of *Tenth United States Census*). He wrote also *Conservation of Water by Storage* (1915).

**SWAIN**, JOSEPH (1857-1927). An American educator, born at Pendleton, Ind. He graduated at Indiana University in 1883, studied in the University of Edinburgh and with the Astronomer Royal of Scotland in 1885-86, was professor of mathematics in his alma mater from 1886 till 1891, and in the latter year was called as professor of mathematics to Leland Stanford Junior University. Two years afterward he returned to Indiana University as president and remained in that position until 1902, when he accepted the presidency of Swarthmore College in Pennsylvania. Dr. Swain served as president of the National Education Association in 1913-14.

**SWAIN'SON**, WILLIAM (1789-1855). An English naturalist, born in Liverpool. He traveled in South America and on his return to England began the publication of works on natural history. In 1841 he emigrated to New Zealand, where he became Attorney-General. Important among his works are: *Zoological Illustrations* (1820); *Exotic Conchology* (1821-22; 2d ed., 1841); *Ornithological Drawings* (1834-41); *Birds of Western Africa* (1837); *The Naturalist's Guide*, etc. (1840).

**SWALLOW** (AS. *swalewe*, Ger. *Schwalbe*, swallow). A passerine bird of the family Hirundinidae, a family represented by many similar species in almost all parts of the world. The

# FAMILIAR SWALLOWS

1. WHITE-BELLIED or TREE SWALLOW (*Iridoprocne bicolor*).
2. BARN SWALLOW (*Chelidon erythrogaster*).
3. PURPLE MARTIN (*Progne subis*).

4. CLIFF or EAVES SWALLOW (*Petrochelidon lunifrons*).
5. BANK SWALLOW or SAND MARTIN (*Riparia riparia*).
6. ENGLISH HOUSE SWALLOW (*Chelidon rustica*).

birds prey on insects, catching them in the air. They have remarkable powers of flight, now soaring very high, now skimming near the earth, and wheeling rapidly. The bill is short and weak, broad at the base, and deeply cleft, so that the gape is wide; the wings are long, pointed, and more or less sickle-shaped when expanded, and have only nine primaries; the legs are short and weak. The tail is generally forked, and the plumage is close and glossy. The family is perhaps the most sharply defined and easily recognized of all in the order. The species are about 80, widely diffused, found in all countries except near the poles. In the colder parts of the world they are summer birds of passage, migrating to warmer regions when winter approaches. Only eight species of swallow occur in North America, and all but one of these winter south of the United States, though in summer they range to the Arctic. The largest species is the purple martin; the smallest the bank swallow (q.v.). Perhaps the commonest of North American swallows is the barn swallow (q.v.). Another swallow numerous about farmyards and barns is the cliff or eaves swallow (*Petrochelidon lunifrons*), whose nest is the remarkable flask-shaped structure of pellets of mud often seen attached in rows to the outside walls of barns, near the eaves. Formerly, as in the case of other swallows (see BARN SWALLOW), this species bred in rocky places and placed its nests in large companies against the faces of cliffs.

A large and handsome swallow common throughout North America is the white-bellied or tree swallow (*Tachycineta*, or more correctly *Iridoprocne bicolor*), steel blue or green above and pure white beneath. Of the same genus is the exquisite little violet-green swallow (*Tachycineta thalassina*) of the western United States, less than 5 inches long; its upper parts are velvety green and violet purple, while the under parts are pure white. The rough-winged swallow (q.v.) completes the list. South America has a large series of swallows similar to those of the United States, and especially of that group of which the tree and violet-green swallows are a type. Some naturally breed in holes of rocks, others in hollow trees, or form nests of mud, straw, and feathers in some similar situation; but nearly all abandon wild ways as the country is settled and place their abodes near buildings. In Great Britain *Hirundo rustica*, the common or chimney swallow (to be distinguished from the American chimney swift, q.v.), is much like the barn swallow and makes a similar nest, usually placed under a shed roof, in a half-ruined building, or often in a chimney. The geographical range of this species extends over a great part of Europe, Asia, and Africa. The window swallow, or house martin (*Hirundo urtica*), is another very common European species, glossy black above, white below and on the rump, the feet covered with short downy white feathers, which is not the case in the chimney swallow. The swallows, because of their insectivorous diet, are of considerable economic value. Flies, mosquitoes, and gnats, as well as many insects injurious to crops, form the bulk of their food. The barn swallow is of particular service about fields of grass, where it destroys the moths of some of the smaller cutworms as they fly low over the grass.

Consult Sharpe and Wyatt, *Monograph of the Hirundinidae, or Family of Swallows* (London, 1885-94), containing a description, with colored

plates, of all the species of the world and a full bibliography, and general ornithologies; also Forbush, *Useful Birds and their Protection*, published by the Massachusetts Board of Agriculture (Boston, 1913).

**SWALLOWTAIL.** Any member of a family of large butterflies, Papilionidae, with tail-like prolongations of the hind wings. Black, yellow, blue, and green are the prevailing colors. About 35 species occur in the United States. South America is most rich in these butterflies. About 850 species have been described in all. The larvæ of the swallowtails possess a curious process on the thorax called an osmaterium, which is usually retracted, but may be thrust forth at will. It is a Y-shaped process and contains a scent gland which emits a strong odor when the organ is thrust out. The pupa is placed with the head upward, fastened by the tail to the supporting object, and is kept in place by a silk band around the middle of the body. (See BUTTERFLIES AND MOTHS, and Colored Plate therewith, Fig. 5.) In certain species the males and females differ so much both in form and coloration that they might easily be mistaken for distinct species. In New Guinea there occurs a swallow-tailed butterfly (*Ornithoptera paradisea*) the female of which is black, white, and gray, and the male is gold and green, with very long tails on the hind wings. The males of another species of the same genus are numerous and the female is rare; the proportion is said to be about 1000 to 15. Not only does the female show sexual dimorphism, but even considerable seasonal dimorphism. The tiger swallowtail (*Jasonides glaucus*) is a North American species which shows a striking sexual dimorphism in a portion of its range. The form now known as *Turnus* is straw-colored above, banded and marked with black. In the South and West black forms of the female sex occur and belong to the so-called *glaucus* form. The caterpillar of these two forms is dark green with two purple eyespots, one on each side of the third thoracic segment, which are bordered with black, yellow, and black again in turn. When not feeding, this caterpillar rests on a bed of silk spun on a leaf. The zebra swallowtail (*Iphiclidea ajax*) presents one of the most striking cases of seasonal dimorphism known among butterflies, so that until the life history of this form was known three different species had been described from it. There are several broods a season, and the last brood winters in the chrysalis stage. The butterflies that appear in the early spring are known as the *marcellus* form and those that appear later in the spring as the *telamonides* form. The latter are larger butterflies with longer tails and more white than the *marcellus* form. (See Colored Plate of AMERICAN BUTTERFLIES.) All the late spring broods produce a third form which is still larger and with longer tails. This summer brood is known as the *ajax* form. See illustration at SKIPPER.

**SWALLOW THORN**, or SEA BUCKTHORN (*Hippophaë*). A genus of shrubs of the family Elæagnaceæ, natives of Europe. The commonest species (*Hippophaë rhamnoides*) is a spiny shrub often planted for ornament in sandy soil, especially near the sea. It is valued for its silvery leaves and yellow, acid, one-seeded berries, which, besides being attractive, are useful for sauces and jellies.

**SWALLOWWORT.** See ASCLEPIAS.

**SWAMMERDAM**, swām'mēr-dām, JAN

(1637-80). A Dutch naturalist, born in Amsterdam. He studied medicine at Leyden, but devoted most of his life to the study of insects and other animals. He was a skilled dissector of small animals and was the father of the scientific study of the morphology and metamorphosis of insects. He first made a natural classification of insects by distinguishing between those which have a complete metamorphosis and those which have not. He wrote: *Tractatus de Respiratione usque Pulmonum* (1667); *Allgemeene verhandeling van bloedeloose diertjes* (1669); *Biblia Naturæ, sive Historia Insectorum in Certas Classes Redacta* (ed. Boerhaave, 1737-38).

**SWAMP** (AS. *swam*, swamp, MHG. *swam*, swamp, Ger. *Schwamm*, sponge). An area of wet ground usually covered with certain coarse grasses, trees, and other plants peculiar to such land. Drainage seems to be the principal controlling factor in producing typically different swamps. In undrained swamps acids and other products of plant decay, together with various root excretions, accumulate, while the soil is relatively cold and poorly oxygenated; hence conditions are relatively unfavorable for plant growth, and many xerophytes (q.v.) are found in such places. River swamps, being comparatively well drained, afford some favorable habitats and are dominated by hydrophytes (q.v.). Swamps abounding in xerophytic plants are peat bogs or moors and salt marshes. In the latter many of the plants are succulents, while the coarse grasses resemble those of the prairies. (See HALOPHYTES.) In mangrove swamps xerophytic leaf structures, kneelike processes from the roots, supposed to be of advantage in aëration and vivipary (q.v.), are among the most interesting features. Cypress swamps of the southern United States show many similar phenomena. (See CYPRESS.) All swamp plant associations may be considered as ephemeral, the areas becoming grassland or forest with the development of the drainage. Consult Eugenius Warming, *Ecology of Plants* (new ed., Oxford, 1909).

**SWAMP DEER**, or BARASINGHA. A deer of northern India, of rather large size, with smooth and somewhat flattened antlers, with a prominent brow tine and sometimes 16 to 20 points. It is a grazer, keeps in the outskirts of the woods, and on grassy lands and in winter gathers into small bands. Its scientific name is *Cervus duvauceli*. Consult R. Lydekker, *Deer of All Lands* (London, 1898), and id., *The Game Animals of India, Burma, Malaya, and Tibet* (ib., 1907).

**SWAMP HARE**, or SWAMP RABBIT. A hare of the swamps of the lower Mississippi valley (*Lepus aquaticus*), 24 inches long, finely mottled above with buff, rufous, and black, and more buff than the cottontail; belly and underside of tail pure white. Its habits are little known. Cf. MARSH HARE.

**SWAMP HONEYSUCKLE**. See HONEYSUCKLE.

**SWAMP OAK**. See CASUARINA.

**SWAMP/SCOTT**. A town in Essex Co., Mass., adjoining Lynn and 13 miles from Boston, on Massachusetts Bay, and on the Boston and Maine Railroad (Map: Massachusetts, F 3). It is attractively situated and is known as a summer resort. There are two parks and a public library. The Phillips School is the most prominent building along the shore. Fishing is of some importance, but the community is engaged largely in the industries of Lynn (q.v.).

The town includes several villages. Pop., 1900, 4548; 1910, 6204; 1915 (State census), 7345.

**SWAMP WARBLER**. A large genus (*Helminthophila*, or more correctly *Vermivora*) of American warblers (q.v.), so called because of their fondness for low, swampy places. They are small, trim, insect-catching migratory birds prevailing gray or green and yellow in color, and most of them breed north of the United States and winter in the tropics. A good example is the goldenwing (*Vermivora chrysoptera*), which is gray on the upper parts and white below, with the throat and auricular region black, and a conspicuous yellow patch on the wing.

GOLDENWING.

**SWAN** (AS., OHG. *swan*, Ger. *Schwan*, swan; probably connected with Lat. *sonus*, sound, Skt. *svan*, to resound). A water bird of the duck family, the seven species of which constitute the subfamily Cygninae. To six of these, English ornithologists give the generic name *Cygnus*, while the Americans call them *Olor*. Swans are larger in body than geese and are recognizable by their long arched necks, enabling them to reach food on the bottom of streams and shallow ponds without diving. They nest mostly in high latitudes, constructing on the ground a rude receptacle of rushes and the like for the half a dozen greenish eggs. They feed chiefly on vegetable substances, as the seeds and roots of aquatic plants, but also on fish spawn, of which they are great destroyers. They hiss like geese and strike with their wings in attack or defense.

The typical and most familiar example of the tribe is the tame or mute swan (*Cygnus*, or *Olor*, *olor*), which is about 5 feet in entire length and weighs about 30 pounds. It is known to live for at least 50 years. The male is larger than the female. The adults of both sexes are pure white, with a reddish bill; the young (cygnets) have a dark bluish-gray plumage and lead-colored bill, surmounted by a black knob at the base of the upper mandible, and with a black nail. (See Colored Plate of WATER BIRDS.) In its wild state this species is found in eastern Europe and in Asia; in a half-domesticated state it has long been a common ornament of ponds, lakes, and rivers. It has a soft low voice, plaintive, and with little variety, heard chiefly when it is moving about with its young.

Swans, according to the law of England, are birds royal; those actually kept by the crown had a mark, and the King's swanherd once was an important person. The royal swans of the Thames are so marked to this day by notches and lines cut upon the beak, and the process of collecting and marking them annually is called upping. Other Old World swans are the whooping swan, Bewick's swan, and the aberrant black swan (*Chenopsis atrata*) of southern and western Australia and Tasmania, which is comparatively small and deep black except the white wing quills and the red bill.

The North American swans are three in number. The most common species (*Olor*, or *Cygnus*, *columbianus*) breeds in the Far North and is seen in the United States only on its migrations, which extend to the Gulf of Mexico, and it is very rare east of the Alleghanies. The

trumpeter swan (*Olor*, or *Cygnus, buccinator*), noted for its sonorous cry, breeds from Iowa and Dakota northward and winters southward to the Gulf. It is one of the largest species, measuring 5½ feet in length. It is extremely rare and apparently on the point of extinction. The black-necked swan is a South American species. Consult C. W. Beebe, "The Swans," in *Tenth Annual Report of the New York Zoological Society* (New York, 1906). See DUCK.

**SWAN, JOHN MACALLAN** (1847-1910). An eminent English painter and sculptor. He was born at Old Brentford, studied at the Lambeth and Royal Academy schools, London, and in Paris with Gérôme and Frémiet, and was influenced by Barye. In 1889 an oil painting, "The Prodigal Son" (Tate Gallery), established his reputation. His sculptured works—in nearly every material—are usually studies of the feline family, and his modeling is broad, flexible, and realistic. "The Jaguar," "Puma and Macaw" (1900), "Wounded Leopard," and "Leopard Running" (1899), are especially important. His subjects in oil include animals, figures, and landscapes and are distinguished by massive, simple treatment and a strongly imaginative element, the color low in tone and well modulated. Notable paintings are: "Ocelot and Fish"; "Tigers"; "Tigers Drinking" (Henry Frick, New York); "Ceylon Leopards" (National Gallery, New South Wales); "Puma and Macaw" (George J. Goukl, New York); "Panthers Resting" (Tate Gallery). Swan was elected to the Royal Academy in 1905 and received numerous honors, including gold medals at Munich and Paris (1900). Consult Baldry, *J. M. Swan, R.A.* (New York, 1905).

**SWAN, SIR JOSEPH WILSON** (1828-1914). An English inventor, born at Sunderland and there educated. He made several inventions of great value, among them the carbon photographic process called autotype, a miner's electric safety lamp, improvements in electro metallurgical deposition, but most notable of all an incandescent electric lamp. In 1879 he exhibited a lamp with a filament of carbon in a vacuum bulb and followed this by various improvements. These inventions brought him many honors, including a fellowship in the Royal Society and knighthood (1904).

**SWAN, KNIGHT OF THE.** A very old and popular myth found in French, German, and English mediæval romances, first mentioned by William of Tyre about 1180. Helias, Knight of the Swan, is one of eight children of Oriant of Lilefort. Seven are changed to swans, one drawing the hero in a boat to become champion for Clarissa of Bouillon, the ancestor of Godfrey, thus connecting the story with the Crusades. After marriage the knight departs when his wife breaks the taboo on his name, a Grail feature common to all variants, as *Lohengrin*, showing its partly Celtic origin. The scene is generally on the lower Rhine, connecting it with the dukes of Brabant and Cleves, whose symbol was a swan. Consult W. W. Newell, *Legend of the Holy Grail* (Cambridge, Mass., 1902), and R. Jafray, *Two Knights of the Swan* (New York, 1910). See CHEVALIER AU CYGNE.

**SWAN, ORDER OF THE.** A religious association of princes and nobles formed in 1440 by Elector Frederick II of Brandenburg for benevolent purposes. It was extinguished during the Reformation, but was renewed in 1843 by Frederick William IV of Prussia as an association,

open to men and women of all creeds, for the amelioration of physical and moral ills.

**SWANMOTE**, swōn'mōt. See FOREST LAWS.

**SWAN PAN.** A Chinese calculating device. See CALCULATING MACHINES.

**SWAN RIVER.** A small river of Western Australia entering the Indian Ocean at Fremantle, 12 miles below Perth. It is navigable to vessels of light draft. On its banks the first British emigrants landed and founded in 1829 the Swan River Colony, which formed the nucleus of the State of Western Australia.

**SWANS.** See SWANITANS.

**SWANSEA**, swōn'sī. A seaport in Glamorganshire, South Wales, at the mouth of the Tawe, 60 miles west-northwest of Bristol (Map: Wales, B 5). Swansea is the chief seat of the tin-plate trade of England and one of the most important copper smelting and refining centres in the world. The vast resources of the surrounding coal field began to be exploited about 1830, and since that time the progress of Swansea has made it next to Cardiff the most important town in South Wales. The principal edifices, for the most part of modern construction, comprise a guildhall with the crown and law courts and municipal offices, the Royal Institution of South Wales, the grammar school founded in 1682, a good public hall, and a spacious and well-arranged infirmary. The harbor is formed by piers of masonry projecting from either side of the mouth of the Tawe into Swansea Bay, a wide inlet of the Bristol Channel. The total tonnage entered and cleared, excluding coastwise vessels, was 4,902,000 in 1913. In the immediate vicinity are smelting works, in which many thousands of tons of copper ores, silver ores, and zinc ores are smelted annually. The total amount of coal exported from Swansea in 1913 amounted to 4,451,597 tons, valued at \$15,734,070. Swansea owes its origin to a castle erected in 1099. In 1260 the castle was burned down. It was twice rebuilt, but was finally dismantled by the Parliamentarians in 1647 and is now an interesting ruin. Pop., 1901, 94,514; 1911, 114,663.

**SWANSON**, swōn'son, CLAUDE AUGUSTUS (1862- ). An American lawyer and legislator, born at Swansonville, Va. He was educated at Randolph-Macon College (A.B., 1885) and, in law, at the University of Virginia. He afterward practiced law at Chatham. A Democrat, he served as a member of Congress from 1893, resigning in 1906 after being elected Governor of Virginia. His four-year term in this office was generally regarded as able. In 1910 he was appointed to fill an unexpired term as United States Senator, and the next year he was elected for a full term. He was considered a conservative in politics, but supported President Wilson. He was chairman of Committee on Public Grounds and Buildings after 1913.

**SWANTON**, swōn'ton, JOHN REED (1873- ). An American ethnologist, born at Gardiner, Me. He was educated at Harvard (A.B., 1896; Ph.D., 1900) and studied also at Columbia from 1898 to 1900. Thenceforth he was connected with the Bureau of American Ethnology, Washington, D. C. In 1909 he served as president of the Folk Lore Society and in 1910 became an associate editor of the *American Anthropologist*. His publications include: *Contributions to the Ethnology of the Haida* (1905); *Haida Texts and Myths* (1905); *Haida Texts—Masset Dialect* (1908); *Tlingit Myths and Texts*

(1909), *Indian Tribes of the Lower Mississippi Valley and Adjacent Coast of the Gulf of Mexico* (1911).

**SWANWICK**, swōn'ŭk, ANNA (1813-99). An English author and feminist, born in Liverpool. In Berlin she studied German, Greek, and Hebrew, and after settling in London took up mathematics also. Her volumes of translations appeared as *Selections from the Dramas of Goethe and Schiller* (1843); *Faust, Tasso, Iphigenie, and Egmont* (1850); complete translation of *Æschylus* (1873); *Faust* (1878). Both in the case of Goethe and of *Æschylus*, her translations still remain of the best. She also assisted in the founding of Girton College and Somerville Hall, Cambridge; advocated the study of English literature in the universities; and signed John Stuart Mill's petition to Parliament for the political enfranchisement of women. To the feminism of her time her career was notably stimulating. Besides her translations, Miss Swanwick published several books of her own writing. Consult Mary L. Bruce, *Anna Swanwick* (London, 1903).

**SWARTHMORE** (swarth'mōr) COLLEGE. A coeducational institution for higher education founded in 1864 by members of the Society of Friends of Swarthmore, Pennsylvania. Until 1903 the college conferred the degrees of Bachelor of Letters and Bachelor of Science. In that year degrees of Bachelor of Arts and Bachelor of Science in engineering were made the only ones given. In 1912 the degree of Bachelor of Science was abolished and since that time the degree of Bachelor of Arts is the degree conferred in all departments. The work is partially elective. The degree of Master of Arts and the degrees of civil, mechanical, and electrical engineers are given for advanced work. In 1915 there were 445 students in all departments with 44 acting instructors and 5 emeritus professors. The college library contained 26,000 volumes. The productive funds amount to \$1,600,000, and the annual income to about \$168,000. The total value of the college property is \$1,800,000. During 1915 two swimming pools, one for the women and one for the men, were added to the gymnasium building. In the same year the Sproul Astronomical Observatory was finished. The equipment of this includes a telescope with an equatorial refractor of 24" aperture and 36' focal length. The president in 1915 was Joseph Swain, M.S., LL.D.

**SWASTIKA** (Skt. *svastika*, of good fortune). A fylfot or four-foot cross, a monogrammatic sign having four branches, of which the ends are bent, generally at right angles,

thus  or . In one form or

another it has been used as a symbol of welfare from a very early time. The sign appears in a variety of modifications, often connected in a continuous scroll, of which there are two types, the European and Asiatic, and the American, as illustrated by the diagrams.

Though the swastika has been found in Europe, Asia, and America, it seems to have been unknown to Oceania; at least up to 1916 no examples had been found there. There is, furthermore, no evidence to show that it was current as a native symbol in Egypt, Babylonia, Assyria, Phœnicia, or (till a late period) in Persia. It was adopted as a sacred symbol by both Jainism (q.v.) and Buddhism (q.v.)

and its presence in China, Japan, and Tibet can easily be explained as due to the latter religion. The swastika is first mentioned in India by

EUROPEAN AND ASIATIC SERIES

Panini (q.v.) in the fourth century B.C., and appears to have been a simple cross, as in crossed arms. Many of the swastikas found at Hisarlik (ancient Troy) were probably not true swastikas. They are not found before the third city. Its original significance is unknown, but

AMERICAN SERIES.

it has been the object of endless speculation. Some scholars see in the swastika a solar symbol, which represents, in its so-called female and male

forms,  and  respectively, the annual

circuits of the sun to north and south, or its daily course across the sky. The swastika has also been interpreted in other ways, as a wind symbol, an earth symbol, an emblem of productivity, a phallic emblem, etc. Temple regards it as in origin merely decorative, and suggests that the running design may have been taken from a coil of string. In the opinion of d'Alviella, who calls it, from its shape, gam-madion, the swastika was chiefly talismanic. It has been derived by some from the cross; by others, from the circle; it has also been regarded as an evolution from the lotus-petal in architecture; and as a mystic design it has been associated with fire and with water. The sun and fecundity are its most probable sources, if it had any meaning beyond that of an ornament becoming a mystic sign. The swastika appeared first in the Bronze age, and occurs in the Swiss

lake dwellings, but, according to the discoveries of Chantre, it seems to have originated in the region of the Caucasus. In the historic period it is found in Japan, Korea, China, Tibet, Armenia, Asia Minor, Greece and its islands (especially Cyprus and Rhodes), Italy, France, Germany, Russia, Scandinavia, Great Britain (perhaps only under Scandinavian influence), North America (in the mounds of Ohio, Tennessee, Mississippi, Alaska), Mexico, and South America (e.g., Brazil). In assigning its original home, it must be remembered that no case of Oriental swastikas precedes the period of Greek influence in India. It seems probable that d'Alviella may be right in ascribing an eastern emigration from a western centre, if not from Troy itself. It is said that there is in Tibet a sect of rationalists called Swastikas, but this is probably an error, and the sect meant is that of the Jains.

Consult: R. C. Temple, *Journal of the Anthropological Society of Bombay*, vol. i (Bombay, 1886); Eugène Goblet d'Alviella, in *La migration des symboles* (Paris, 1891); also Thomas Wilson, "The Swastika, the Earliest Known Symbol, and its Migrations," in United States National Museum, *Annual Report*, 1894 (Washington, 1895); Léon de Milloué, "Le Svastika," in *Annales du Musée Guimet*, vol. xxxi (Paris, 1909).

**SWATOW**, swā'tou' (a local corruption of Chinese *Shan-t'ou*, fish-trap head). A treaty port in the Province of Kwangtung, southeast China, situated on the left bank of the river Han near its mouth (Map: China, L 7). It was opened to foreign residence and trade by the treaty of Tientsin (1858), and the British and United States consuls were appointed in 1860. The foreign community is small and isolated, partly in the vicinity of the native town and partly on the hilly ground on the opposite side of the river. Sugar making is the chief industry of the region served by Swatow. Sugar is the heaviest export, and bean cake from Niuchwang, for use as manure in the sugar fields, is one of the heaviest imports of native products. There are several large sugar refineries here, and a steam flour mill. Other products are tea, grass cloth, indigo, vegetable oils, paper, tobacco, joss sticks, joss paper, etc. Pop., 1910, 66,000. In 1912, foreign and Chinese exports amounted to 41,209,329 Hk. taels, and imports to 16,181,795 taels (Hk. tael = \$0.728).

**SWATS**, swāts. A people of the Indo-Afghan frontier, constituting a branch of the Yufufzais, who belong by race and language to the Ayran stock. Their country, called Swat, traversed by a river of the same name, an affluent of the Kabul, is included in the Northwest Frontier Province of India. After having been nearly exterminated at the end of the sixteenth century, the Swats came under the religious dominance of Abdul Ghafur (1794-1877), who was practically their ruler during his last years. Fanatical Mahomedans, the Swats gave the British government much trouble in 1895 and 1897. See AFGHANISTAN; ARHUND OF SWAT.

**SWAZILAND**, swā'ze-lānd. A British protectorate in South Africa (Map: Cape of Good Hope, K 6). The area is stated at 6536 square miles. The country consists of three distinct regions: a mountainous region in the west reaching an altitude of over 4000 feet; the Middle Veld, about 2000 feet lower; and the Low Veld, having an average altitude of about 1000

feet and bounded on the east by Lebombo Mountains. The first two regions are well watered and healthful, and adapted for agriculture and grazing. The natives raise insufficient crops of corn, millet, sweet potatoes, groundnuts, etc. The estimated number of cattle in 1914 was 73,000, and of native sheep and goats 170,000. Upward of 150,000 merino sheep are brought in annually from the High Veld for winter grazing. Gold and tin are worked at several localities; in 1913-14 the output of tin amounted to 493 tons, valued at £51,220, and of gold, 11,325 ounces, £48,105. Since 1910 the country has been treated for customs purposes as a part of the Union of South Africa. By an Anglo-Boer convention of 1894 Swaziland was placed under the administration of the South African Republic. Administration passed to the Governor of the Transvaal in 1903 and to the High Commissioner for South Africa in 1906. The laws of the Transvaal were extended to Swaziland; except where modified by statute, the Roman-Dutch law is in force. In 1907 the paramount chief and other chiefs were confirmed in their civil jurisdiction over natives, subject to appeal to a British resident commissioner. British headquarters are at Mbabane; this and Bremersdorp, the old capital, are the only European villages. The Swazis are an intelligent tribe akin to the Zulus; in 1911 they numbered 98,733. Population as returned by censuses of 1904 and 1911 respectively: European 890 and 1083; other, 84,601 and 98,876; total, 85,491 and 99,959. Estimated total in 1914, 107,117.

**SWEARING, PROFANE.** See BLASPHEMY.

**SWEAT** (AS. *swāt*, Ger. *Schweiss*, sweat; connected with Lat. *sudor*, Gk. *ἰδρώς*, *hidrōs*, sweat). The fluid excreted through the pores of the skin; perspiration. The nature, composition, and uses of this fluid in the normal state have been noticed in the article on SKIN (q.v.). Sweat is diminished in amount in many febrile diseases, especially if the temperature is high and fever prolonged. Anhidrosis, as this condition is called, accompanies diseases in which there is a profuse discharge of fluid from the kidneys, as in diabetes, or from the bowels or stomach. In anasarca or general oedema and myxedema sweat is diminished from stretching of the skin. Certain drugs, as belladonna and strychnine, markedly diminish the amount of sweat; others, notably pilocarpine, increase it. Profuse sweating (hyperhidrosis) occurs in acute rheumatism, Asiatic cholera, and certain adynamic fevers, the sweating stage of malaria, the advanced stages of pulmonary phthisis, and septicæmia. Certain ailments are characterized by localized sweats: the hands and feet in conditions of general debility; the head in rickets; and unilateral or one-sided sweating of the head or face or body in some nervous diseases, or from pressure on the sympathetic nerves by thoracic aneurysm. The composition and color of the sweat may rarely undergo remarkable alterations. When through disease the action of the kidneys has become impaired the sweat has sometimes a urinous odor and deposits white scales or urinary solids upon the skin. This is known as uridrosis. Bromidrosis is an affection of the sweat glands characterized by offensive-smelling perspiration. Hæmatidrosis (bloody sweat) is a rare phenomenon in which blood exudes from the sweat pores. It is seen in young, hysterical women, and has been observed on the face, hands and

feet, ears and umbilicus. Chromidrosis or colored sweat may arise from various causes. The secretion may be red owing to the action of *Bacillus prodigiosus*; in copper workers the perspiration is frequently green in color; in idiopathic chromidrosis the secretion is black or sepia colored.

**SWEATING SICKNESS.** An extremely fatal epidemic disease which prevailed in Europe, and especially England, during the fifteenth, sixteenth, and part of the seventeenth centuries. From the fact that the English people both at home and abroad were chiefly attacked, the malady was known as the English sweat or English ephemera. It first appeared in August, 1485, in the army of Henry VII, shortly after his arrival in Wales from France to fight the battle of Bosworth, and in a few weeks it had spread to London. It was a violent inflammatory fever, attacking as a rule robust, vigorous men, and characterized by a short chill, painful oppression over the epigastrium, headache, stupor, and a profuse fetid sweat. The disease took its course in about 24 hours. The patient suffered profound prostration and intense internal fever, but refrigerants seemed only to do harm. This epidemic lasted about a month, but during this short period many thousands died. The disease returned to England in 1506, 1517, 1528, and 1551. The epidemic of 1528 was particularly severe and was long referred to as "the great mortality." It raged throughout Europe. In Hanover alone 8000 persons died. After 1551 no further epidemic occurred until the beginning of the eighteenth century. The disease is nearly always prevalent in some part of the world, most frequently in France (Picardy) and Italy, under the more modern name of miliary fever. (See MILLARIA.) An epidemic occurred in France in 1906, through transmission by rats or field mice and their fleas. A year before this there was a small epidemic of 126 cases in Austria. In Germany it is still known as the English sweat. As now observed, the disease is characterized by fever, profuse sweats, and an eruption of miliary vesicles. As in influenza a large number of people are attacked, but the epidemic soon passes and the mortality is not high. Consult: J. F. K. Hecker, *Epidemics of the Middle Ages* (Eng. trans. by B. G. Babington, published by the Sydenham Society, 3d ed., London, 1859); August Hirsch, *Handbook of Geographical and Historical Pathology* (Eng. trans. from 2d Ger. ed. by Charles Creighton, published by the New Sydenham Society, 3 vols., ib., 1883-86); Charles Creighton, *History of Epidemics in Britain* (ib., 1891); William Osler, *Modern Medicine* (Philadelphia, 1914).

**SWEATING SYSTEM.** The practice pursued by certain manufacturers, particularly of clothing, of giving out piece work to individuals on which the work is to be done at home and at starvation wages. The system is a survival of the household form of industry that still exists in certain trades in large cities. The term sweater was used first by journeymen tailors in London, who worked long hours. As more work was given out, the home worker employed his family and outsiders, and thus a system of subcontract developed in which the middleman was called the sweater. Evils of the sweatshop are long hours—10 to 18 hours a day, including Sunday; overcrowding in shops and surrounding tenements; unsanitary conditions in work

rooms and tenement houses, lacking in light, air, and cleanliness; child labor, young girls and boys often running the machines; disease and deformity brought on by confinement and dust; irregularity of work; and poor pay. The chief causes of the sweating system are (1) the excessive supply of unskilled labor; (2) an economic advantage to large dealers, in having their work done in small shops, thereby saving rent and evading factory laws, in cheap labor, in the inability of isolated workers to combine, and in the irregularity of work; (3) finally, the irresponsibility of employers, and public indifference.

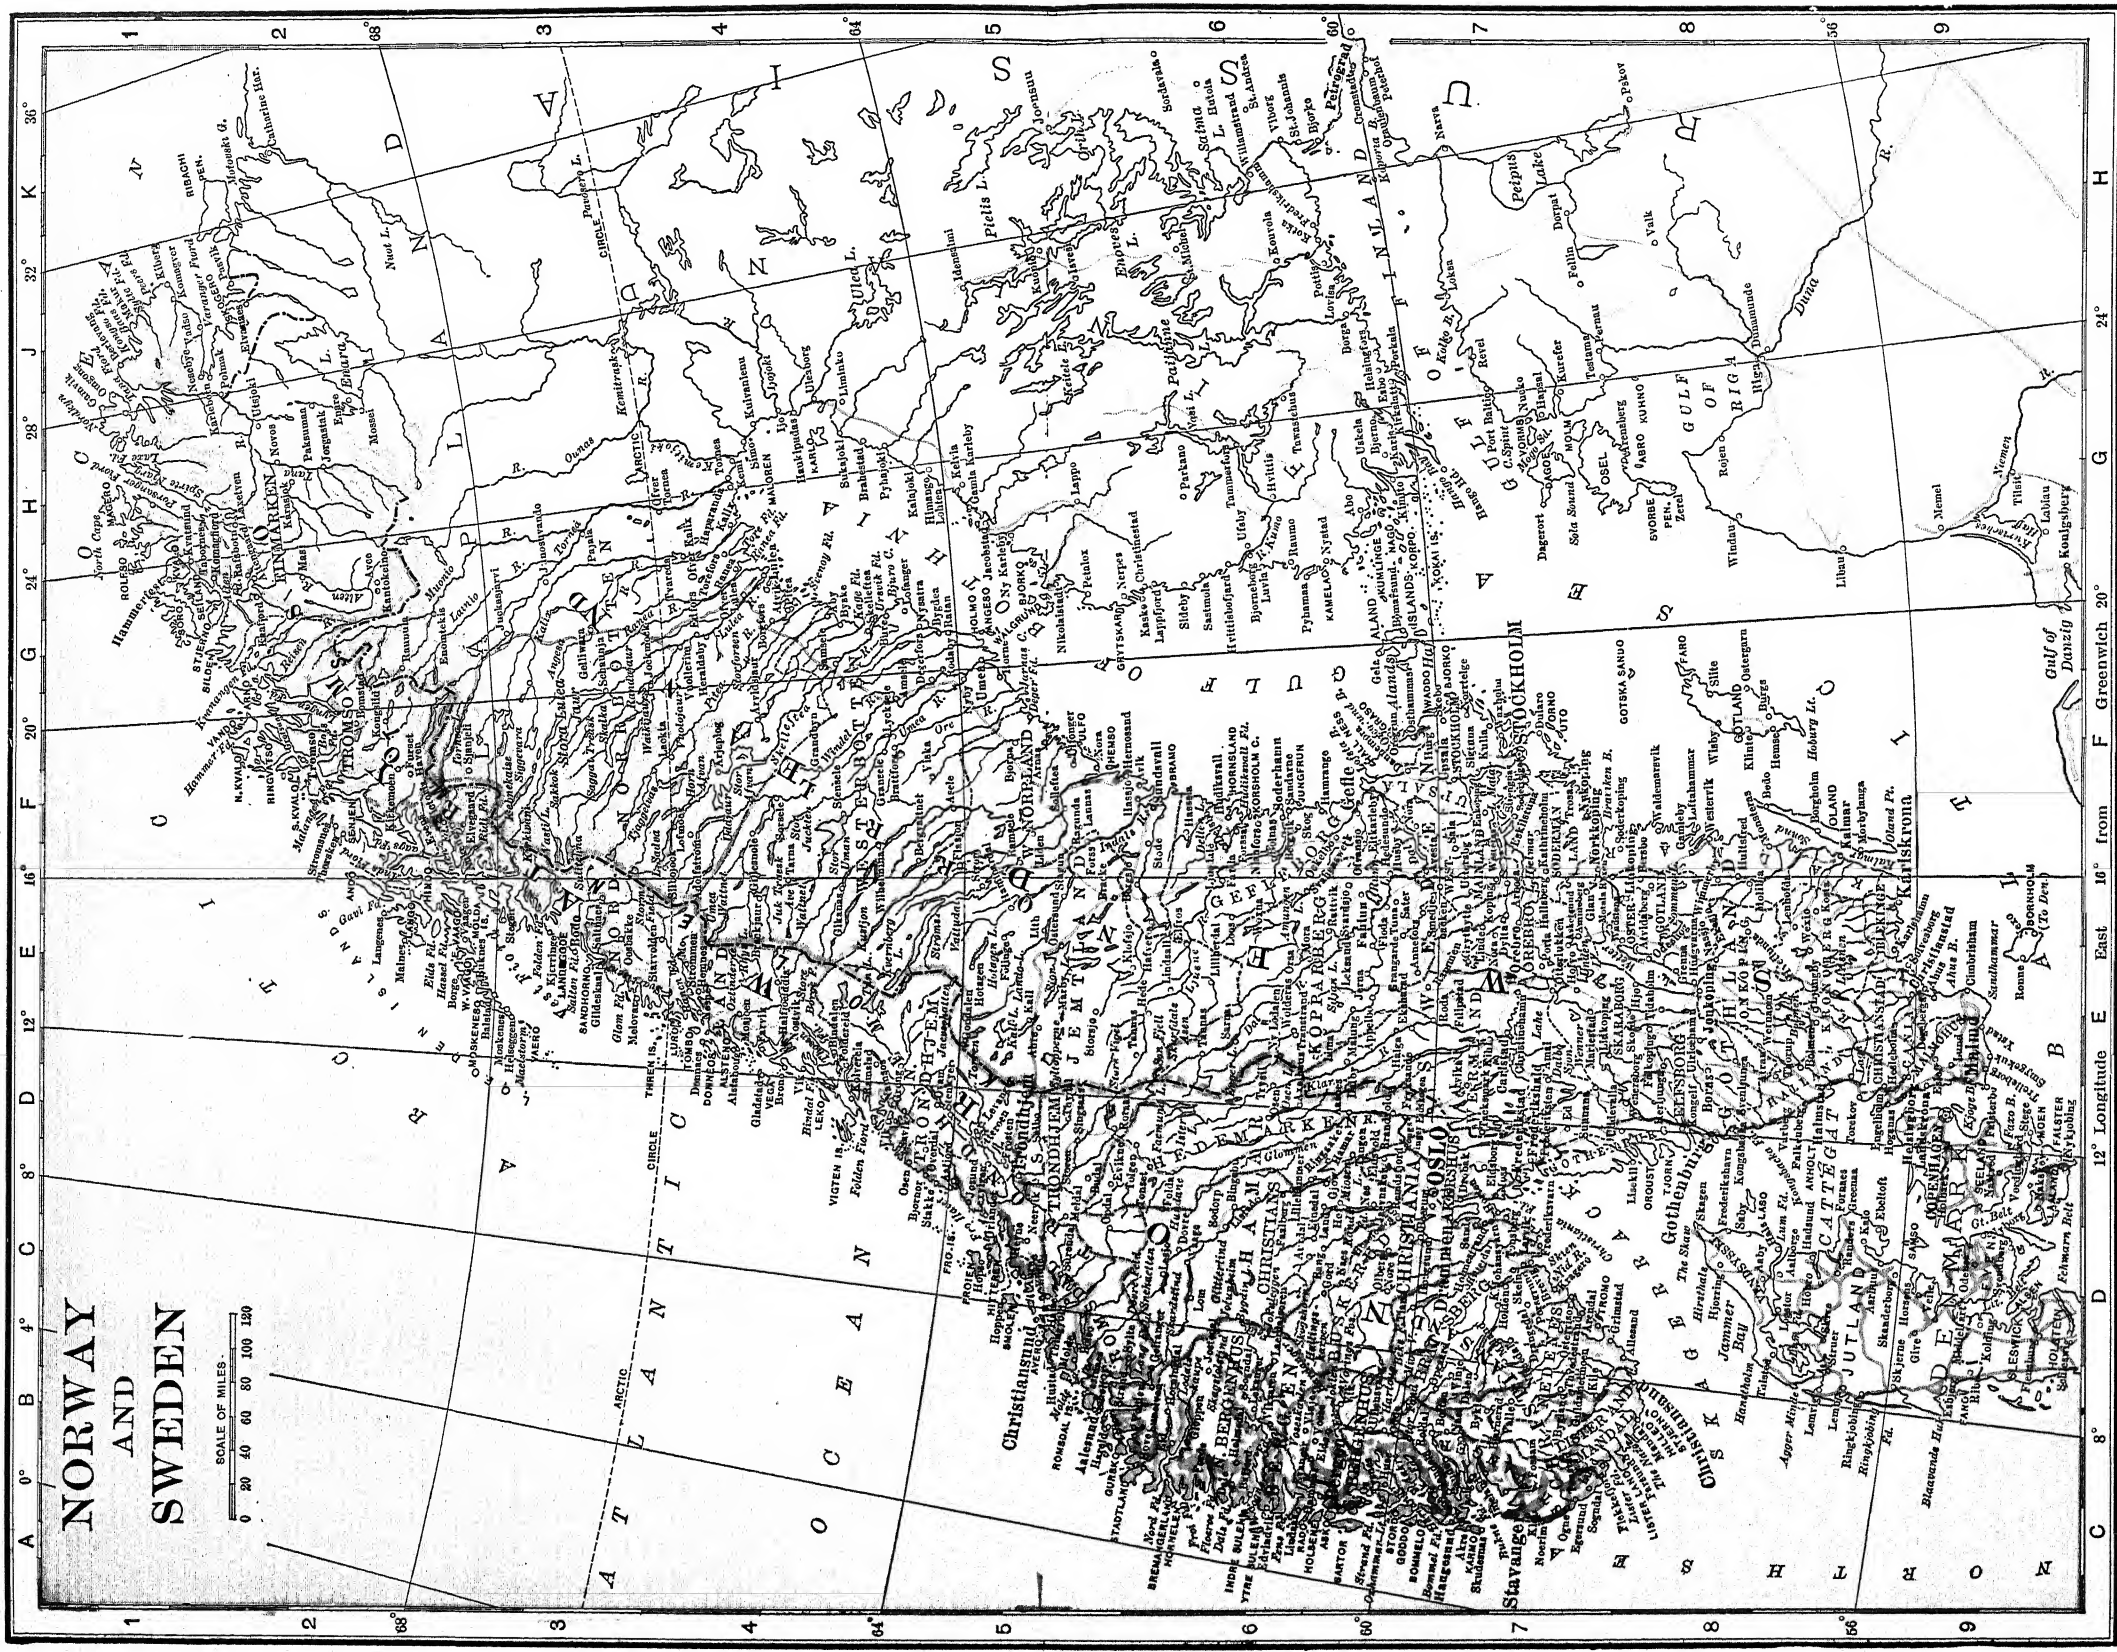

Among proposed remedies may be mentioned (1) stringent legislation, backed by public opinion, to force these kinds of work into large shops and factories; (2) coöperative production; (3) trade unions for unskilled workers; (4) public workshops; (5) restriction of foreign immigration; (6) an eight-hour day; (7) consumers' league. Factory laws of Ohio, Massachusetts, Illinois, and New York require licenses, or permits, describing rooms in which it is proper for work to be done. See CONSUMERS' LEAGUE; FACTORIES AND THE FACTORY SYSTEM; FACTORY INSPECTION; LABOR PROBLEMS.

**SWEATMAN**, swēt'man, ARTHUR (1834-1909). A Canadian Anglican archbishop. He was born in London, England, was educated at Christ's College, Cambridge, and, after his ordination as a priest of the Church of England, was successively curate at Islington and Canonbury. Going to Canada in 1865, he became in the same year headmaster of Hellmuth Boys' College, London, and in 1871 mathematical master in Upper Canada College. He was rector of Grace Church, Brantford (1872-76), archdeacon of Brant (1876-79), was elected Bishop of Toronto in 1879, and in 1907 became Archbishop and Metropolitan and Primate of All Canada.

**SWEDEN** (Sw. *Sverige*). The country occupying the eastern and larger part of the Scandinavian peninsula. It extends from lat. 55° 20' to 69° N., and from long. 11° to 24° E. Area, 172,963 square miles. In several physical aspects it differs much from Norway. It contains more level land and is more fertile and therefore adapted to support a larger population. Its coasts are not so deeply indented; its climate is continental instead of oceanic; and its harbors may be blocked with ice for five months, while those of Norway are unfrozen. Sweden comprises three main divisions. The north half, which is very scantily inhabited, is called Norrland. The south half comprises Svealand (Svearike), in the north, and Gotland (Götarrike), in the south.

**Topography.** The area of all the islands that are a part of Sweden is about 3000 square miles. A group of islands without mountains or vegetation lie off the shore of Göteborg; and the entire Baltic and Bothnia shore is lined with many islets, chiefly low rocks in shallow water, remnants of the Swedish plain. Two large islands in the Baltic lie off the southern part of Sweden. The smaller, Öland, a narrow strip of land, 80 miles long, was once a part of the chalk shore of the mainland, from which it is separated by only 2 miles at the narrowest part of Kalmar Sound. The other, Gotland, is farther at sea, but connected with the mainland by a submarine bank. Only a comparatively small part of Sweden is mountainous—the portion lying along the Norwegian border, and forming the watershed of the peninsula and the boundary between Norway and Sweden for the greater part of its length. (See NORWAY, *Topography*.) The greatest heights are in the north, Kebnekaise (7004 feet) and Sarjettjokko (6988 feet). In the south is a hilly district rising from a plateau several hundred feet above the surrounding plains of the coast, and separated from the mountains of the north by the great depression occupied by the southern lakes. Most of the remainder of Sweden is a plateau sloping rapidly from the mountain fringe to a plain which stretches along the east coast to the southern extremity of the country, and which includes the fertile lowlands of Gotland, strewn with boulders, where the largest and most productive farm lands are found.

**Hydrography.** Sweden is rich in streams and in lakes. Many rivers flow from the mountains southeast to the Gulf of Bothnia or the Baltic, affording much water power, but little navigation, on account of their rapid fall. They pass through many lakes, particularly in their upper courses, and the lakes have the effect of equalizing the floods so that the rivers are quite regular in their discharge. Numerous falls and rapids give a picturesque charm. The Klar Elf (clear stream), the largest river, flows south into Lake Vener. The Göta Elf, which discharges the waters of Lake Vener into the Cattegat, is more important, because its falls and rapids have been circumvented by canals, making it a part of the waterway system of south Sweden. The principal river emptying into the Baltic is the Dal Elf. Many of the Swedish lakes are large and beautiful, distinguished by clear water and picturesque surroundings. The four great lakes of the country lie in the depressed area north of the plateau of southern Sweden. Lake Vener, the largest of them, is the third largest in Europe (2100 square miles). Lakes Vetter (730 square miles), Hjelm, and Mälär (about 670 square miles) drain into the Baltic.

**Climate and Soil.** As the western mountains shut off the tempering influence of the Atlantic, the climate has a continental character. The country being in the latitude of Labrador, the summer is short and the winter is cold and long. At Stockholm the mean temperature in January is about 25° F. and in July about 61° F. The mountains prevent the greater part of the precipitation from reaching the eastern plateaus and plains, so that the mean rainfall in Sweden is less than 20 inches. The greatest rainfall is on the southwest coast, facing the Cattegat, where the average is 35 inches annually, while on the Baltic coast at the same latitude but

13 inches is the average. The country is almost completely covered with snow in winter, when snow traveling on ski is a favorite amusement. The splendid and extensive forests and the farms of Gotland and Scania, where the grain fields return as much to the acre as in England, show that the soils of the central and southern parts of the country are not deficient in fertility.

**Flora.** Forests cover about 51.9 per cent of the country, pines and firs predominating, and extend beyond the Arctic circle. Over 2000 European plants have their northern limit in the Scandinavian peninsula. In Sweden beeches are found only in the extreme south, the oak disappears a little north of Stockholm, while the pine, fir, and alder extend nearly to the limit of arboreal vegetation. The forests of the southern plains differ little in appearance from those of the more temperate parts of Europe, but farther north, in the region of prevailing conifers, the labyrinth of moss-covered boulders, amid which the towering trees rise, where even a path is scarcely possible, gives a special character to the woodlands. The Dal Elf, north of Stockholm, is practically the northern limit of wheat, but barley is grown to the Arctic circle.

**Fauna.** The bounties paid for bear, lynx, wolf, and fox skins and for birds of prey have resulted in nearly exterminating the leading wild animals. The beaver and hare survive, but the wild reindeer is no longer found. Fish are much less abundant in Swedish than in Norwegian waters.

**Geology and Mineral Resources.** Archean rocks are predominant, and in some districts, especially around the great lakes, they are overlaid by Cambrian and Silurian formations. In large areas also the ancient rocks are covered by extensive glacial deposits of clay, sand, gravel, and erratic boulders. Triassic, Jurassic, and Cretaceous rocks appear only in Scania, in the extreme south. Some time after the glacial epoch the Scandinavian peninsula subsided till the sea level, in relation to the land, stood 500, 700, and in some places 1000 feet higher than before, as is shown by marine terraces and marine deposits resting on rocks that had been scarred by glacial ice. Then the land began to rise again and the gradual upheaval is still in progress. The movement is best observed, of course, along the coasts. It is nowhere so rapid as on the Swedish side of the Gulf of Bothnia, and it is most rapid at the northern extremity of the gulf, where the upheaval is estimated at about 5 feet in the past century. In the extreme south no change of level has been observed. Thus the Gulf of Bothnia appears to be slowly draining into the southern basin of the Baltic.

The mining industry competes with difficulty against the powerful rivalry of the leading European countries, although it is more important than that of Norway. Sweden is poorly supplied with coal (only 333,832 tons having been mined in south Sweden in 1910). Manufacturers are compelled to import coal or use charcoal. The most important and valuable mineral product is iron. In 1910, 6,674,670 tons of iron ore were mined in the Kingdom. While about 1,000,000 tons are mined every year near Gefle, Falun, and Dannemora, the largest supply comes from Gellivare, about 130 miles north of the Arctic circle. Swedish iron is regarded as unsurpassed in the world, as it is almost entirely free from phosphorus (0.05 per cent or less), and is

therefore of superior value for the manufacture of steel. For this reason it now rivals the ores of Spain in British and German markets, and large quantities are exported. Magnetite and manganese ores (6341 tons of manganese in 1910) used in steel making also abound. The copper industry of Falun was long widely renowned, but the yield was formerly much larger than at present. Three-fourths of the total yield of zinc ore (54,523 tons in 1910) is produced at the Ammeberg mines, on the north side of Lake Vetter. The yield of lead in 1910 was 355,400 kilograms. The number of persons engaged in mining declined from 35,000 in 1890 to 29,990 in 1910. In 1910 there were 529 mines and iron-works, with 112 smelting furnaces. The value of the mining industry in 1910 was \$60,781,600. The earnings of the mine owners in the same year was \$6,686,666.

**Agriculture, Live Stock, and Fisheries.** Nearly one-half of the population support themselves by agriculture, though only about 12

	Area (acres)	Yield (bushels)
Wheat . . . . .	287,533	9,106,624
Rye . . . . .	910,393	21,816,304
Barley . . . . .	441,488	15,388,728
Oats . . . . .	1,973,678	80,981,176
Mixed grain . . . . .	422,741	18,289,704
Pulse . . . . .	55,822	1,233,000
Potatoes . . . . .	383,270	683,727,000

per cent of the land area is under cultivation. Natural meadows cover 3.5 per cent of the surface, tilled fields 8.9 per cent, forests 51.9 per cent, and 35.9 per cent is unproductive. In 1910, 356,956 farms were under cultivation, of which about two-thirds were from 5 to 45 acres in extent. The preceding table shows the area (in acres) under the chief crops and the yield (in bushels) in 1913. The value of the cereal crops, in 1913, was estimated at 336.8 million kronor, and of all crops at 879.7 million kronor.

The largest and most productive area of farm lands is in the East and West Gotland and Scania, in the south of the country. Despite improvements in farming, especially through importation of modern farm machinery and implements, the country cannot produce wheat and rye enough for home consumption, and large quantities of breadstuffs are brought in every year, chiefly from the Baltic countries. Nearly half the total grain raised is oats—an export crop. The sugar beet thrives in the extreme south, but the acreage given to it does not supply the demand for sugar. Flax, tobacco, and hops are cultivated with success. The value of the agricultural products of 1910 was \$211,206,000. At the end of 1913 Sweden had 596,072 horses, 2,719,018 head of cattle, 985,932 sheep, and 968,888 hogs. Great quantities of butter are exported to Great Britain. The government has done much to improve agriculture and by the appointment of peripatetic teachers. The fisheries are important, though inferior to those of Norway. They do not suffice for the needs of the country. On the other hand, the timber trade is of much greater value than that of Norway.

**Manufactures.** Although the manufacturing industries have been stimulated in every way by the government and have made great progress,

Sweden is still largely dependent upon foreign countries for most of these commodities. The Kingdom lacks the coal, population, and capital for the most successful development in this respect. The industrial advance, however, has been most substantial, as is seen from the following comparisons: From 1905 to the close of 1910 the number of manufacturing establishments changed from 11,949 to 11,435; the number of workpeople in them increased from 280,995 to 302,157, and the total value of the product from \$323,292,200 to \$429,805,990. The saw mills in 1910 contributed \$48,910,500 of the total value of product; flour mills, \$28,523,500; textile mills, \$56,182,500; machine shops, \$35,573,800; and iron and steel manufactures and foundries, \$34,839,800. The timber industry in all its branches, including wood pulp, is the leading manufacturing industry. The public forests (area, 22,111,000 acres) yielded 3,912,800 cubic metres of timber in 1910. In 1910, 39,605 workpeople in 1232 saw and planing mills produced lumber worth \$48,915,800; furniture and other woodwork were also large products. Swedish matches, everywhere famous, are produced chiefly at Jönköping, where one factory employs 1500 hands. There are woolen and cotton factories at Norrköping, Stockholm, and Göteborg, but the manufacture of linen, a household industry, is the only branch of textile manufacture which meets the domestic demand. The most famous ironworks are near Eskilstuna and the chief machine shops at Motala. Swedish bar iron, steel goods, blades, armor plates, cables, nails, and knives are highly esteemed.

**Commerce.** The average annual trade (in million dollars) is as follows:

	1881-85	1891-95	1905	1910	1913
Imports . . . . .	85.5	97.5	156.1	180.1	226.9
Exports . . . . .	67.5	88.5	122.0	158.9	219.1

The Kingdom sells abroad the abundant product of its forests, iron and zinc mines, dairies, and oat fields. Its home supplies of textiles, wool, machinery, railroad iron, and many other things are inadequate, and it must supplement them by foreign purchases. The table (page 721) gives the value in kronor of the leading imports and exports, 1900 and 1910 (a krona equals in value 26 $\frac{7}{8}$  cents). Its trade is chiefly with the countries bordering on the Baltic and North seas. The value of its trade in 1900 and in 1910 with leading countries is shown in the lower table on page 721.

The exports of the United States to Sweden in the calendar year 1903 were \$5,806,000, and the imports were \$3,584,000; in 1906 the exports to Sweden were \$9,073,000 and the imports were \$3,943,000; in the fiscal year of 1910 the exports to Sweden were \$5,991,896, and the imports were \$6,830,477; in 1914 imports, \$11,590,107; exports \$14,644,226. During the Great War the United States exports to Sweden greatly increased, being in the calendar year 1915 \$84,806,759. Among the things that the United States sells to this country are provisions, wheat, machinery, tools, and cotton.

**Transportation and Communication.** Railroads are cheaply built, because of the small cost of land, lumber, and iron. Uninterrupted rail communication extends between Gellivare in the north and Malmö in the south, over 1200 miles.

A line has been constructed from Gellivare to Ofoten Fiord, Norway, giving the iron ore of north Sweden an outlet on the Atlantic coast. The total length of railroads in 1910 was 8643

own government. The fundamental laws of Sweden have never been embodied in any single written constitution, but consist of various enactments of the Diet from 1809 to 1863. By the

miles, of which the state owned 2761 miles. Southern Sweden has an excellent system of waterways by which a series of canals and canalized rivers unite the great lakes with both the North and Baltic seas, providing 2500 miles of interior navigation. In 1910, 140,177 ships and boats passed through the canals. Swedish trade is predominantly maritime, and Swedish vessels are engaged in both home and foreign trade. The mercantile fleet in 1910 comprised 2840 vessels, of 769,985 tons, including 1214 steamers, of 593,073 tons. Göteborg is the principal port, with Stockholm, Malmö, and Helsingborg following. The tonnage entered and cleared (1910)

fundamental laws a limited monarchy is constituted, at the head of which is a king, who is required to be a member of the Lutheran church and who is bound by oath to observe the laws of the land. By the law of succession women are excluded from the throne. In case of failure of succession the King is to be chosen by the Swedish Diet. The King has the exclusive right of legislation as regards trade, commerce, manufacturing, mines, and forests. He is also empowered to issue police regulations and to make rules concerning vagrancy, sanitation, protection against fire, etc. In legislating on other matters he must act with the consent of the Diet. He possesses

was 22,095,228, over one-half in Swedish bottoms.

**Banking.** The National Bank of Sweden (Riksbank) belongs to the state, regulates financial relations with foreign countries, receives private accounts, and lends money on security to nonspeculative enterprises. The bank is under the guarantee of the Diet, its capital and reserve are fixed, and its note circulation is limited by its metallic stock and its current accounts. Its actual circulation is kept far within the authorized limit. The assets and liabilities of the Swedish banks balanced (in kronor) on Jan. 1, 1914, as follows: National Bank, 430,296,681; private banks, 860,857,774; joint-stock banks, 1,987,255,225. The savings banks (exclusive of post office) had, at end of 1913, 1,738,438 depositors, and deposits of 961,798,726 kronor. At the end of the same year the Post Office Bank had 578,254 depositors and deposits of 48,075,655 kronor.

**Government.** From 1814 to 1905 Sweden was united with Norway under a common king, but each was in effect a separate kingdom with its

the right to declare war and make peace upon the advice of a Council of State. He nominates higher officials, military and civil, negotiates treaties with foreign countries, and presides in the Supreme Court. He is advised and in some manner assisted by a Council of State consisting at present of 11 ministers, at the head of which is the Minister of State. They have seats in the Diet with the privilege of debate and the right to initiate legislation. They sometimes resign in case of serious disagreement with the Diet, but the principle of ministerial responsibility is not yet freely recognized. Every new law must have the assent of the crown.

The National Parliament or Diet (Riksdag) consists of two Chambers, both of which are representative in principle. The Upper Chamber consists at present of 150 members chosen for a term of six years by the provincial legislatures (Landstings), 25 in number, and by the municipal governments of those towns which are not represented in the provincial assemblies. These towns are Stockholm, Göteborg, Malmö, Norrköping, and Gelle. The members are distributed

on the basis of one to every 30,000 of the population, and are required to be 35 years of age and in the possession for at least three years prior to their election of property of the taxable value of about \$22,000, or an annual income of about \$1100. They receive no compensation for their services. The Lower Chamber consists at present of 230 members chosen for a term of three years. Of these, 80 are chosen by the towns and 150 by the rural districts. The rural members are distributed on the basis of one member to

munes there is almost complete local self-government, all taxpayers being voters. Some of the communes have primary assemblies very much like the town meetings of New England, while those which are larger and more populous have municipal councils. In the parishes there are local assemblies for regulating ecclesiastical affairs. See paragraph on *History*.

**Finance.** The sources and amount of revenue and the expenditures for 1907 and 1912 were as follows:

REVENUE	1907	1912	EXPENDITURE	1907	1912
	<i>Kronor</i>	<i>Kronor</i>		<i>Kronor</i>	<i>Kronor</i>

every 40,000 inhabitants, while the towns are allowed one member for every 10,000 of the population. All native Swedes 21 years of age possessing property of taxable value of about \$280, or who cultivate for a period of five years a certain amount of land, or who pay an annual income tax on an income of about \$225, are qualified voters. Any elector 25 years of age is qualified for membership in the Lower Chamber. At the election to the Lower Chamber, in 1914, 760,000 votes were cast and approved out of 1,092,000 having the right to vote. The two Chambers never meet in joint session. The members of the Second Chamber receive compensation.

The union of Norway and Sweden under the same executive made necessary some provision for the administration of those affairs which were common to both monarchies, such as the conduct of their foreign relations. In this domain the King was given power to act for both countries, but his action was subject to the approval of the joint Council of State. Thus, he might declare war and make peace, send and recall ambassadors, use ships of war, etc., with the consent of the joint Council. This did not, however, destroy the individuality of either nation as regarded foreign affairs, since the King might conclude treaties which affected but one of his kingdoms. Matters of common interest not within the power of the King were regulated by concurrent action of the two Diets. For the purposes of local administration Sweden is divided into 24 läns or provinces, each under the supervision of a prefect nominated by the King. In each province there is a general council or Landsting, which regulates internal affairs. The city of Stockholm, the capital, constitutes a separate administrative division. In the com-

On Jan. 1, 1914, the public liabilities, contracted entirely for productive purposes (railroads, etc.), were 622,560,572 kronor, bearing interest at from 3 to 4½ per cent. All loans are paid off gradually by means of sinking funds. On Jan. 1, 1914, the total assets of the state were 1,927,457,433 kronor. Thus, the financial condition of the state showed a surplus of assets of 1,304,890,861 kronor.

**Weights, Measures, and Money.** Gold is the standard of value. The krona, the unit of coinage, is worth 26⅞ cents. The metric system of weights and measures became obligatory in 1889.

**Army.** In 1915 the total peace establishment consisted of 3027 officers, 2010 noncommissioned officers, and 70,218 enlisted men. Total, 75,255. On initial mobilization it is expected that the field army would amount to about 100,000 combatants, composed of 6 divisions, each of 2 brigades of 2 regiments (12 battalions in all), with a regiment of cavalry (4 squadrons), a regiment of field artillery (11 batteries of 4 guns each), a company of engineers, a pontoon train, a telegraph detachment, a supply company, a bearer company, an ammunition column and train. Added to this would be one independent cavalry division of 4 regiments, and another cavalry division of 16 squadrons and 3 horse batteries. Total about 100,000 combatants. The first uppbåd (category) of the active army would be able to furnish an equal number of reserve troops. Total for the first uppbåd of the Beväring or active army, including the peace establishment, about 275,000 officers and men. In addition to this force the third reserve (or Landstorm) would supply about 170,000, giving in all about 445,000 officers and men. The

total carried on the rolls, including administration personnel, is about 485,000. Of this number, however, only about 100,000 are supposed to be available for immediate use in the field army. Service is both voluntary and compulsory, the former class (about 20,000 officers and men) comprising the permanent personnel of the skeleton organization maintained in time of peace as a training school for the yearly conscript contingent. Liability is for 23 years, from the age of 20 to 42 inclusive. The men pass through the following categories: first uppbåd of the Bevåring (active army), 11 years; second uppbåd, 4 years; Landstorm, 8 years. Initial training: infantry, 250 days; cavalry and field artillery, 281 days; garrison artillery and engineers, 295 days. Subsequently infantry has 4 trainings, 3 in the first period for 30 days each, 1 later for 15 days. Cavalry and artillery have 3 trainings, 2 of 42 days and 1 of 25 days. Arms: infantry, 6.5 mm. Mauser; field artillery, 7.5 cm. Q. F. Krupp gun.

**Population.** The population, according to the census of 1910, was 5,522,403. The density of population is 31 to the square mile. The growth of population has been as follows: 1800, 2,347,303; 1840, 3,138,887; 1890, 4,784,981; 1910, 5,522,403; 1920, 5,903,762. Emigration is chiefly to the United States and averages about 20,000 annually. In 1913 the emigration to the United States was 16,329.

**Religion.** The Lutheran church is recognized as the state religion, and most of the people are professors of that faith. There were a few followers of the Roman Catholic and other faiths. In the state church are 13 bishoprics and 2513 parishes.

**Education.** Education is maintained at a high level. It is under the control of the government, is compulsory, and practically all the inhabitants of school age and over can read and write. The secondary schools and the universities are modeled on the German system. In 1913 there were 2461 students in the University at Upsala and 1378 in the University of Lund. The schools included in 1913: 82 public high schools, 24,129 pupils; 44 people's high schools, 2619 pupils; 15 normal schools for elementary teachers, 1913 pupils; 2 high and 8 elementary technical schools; 10 navigation schools, 333 pupils; and besides schools for deaf-mutes and the blind, medical, military, agricultural, veterinary, forestry, weaving, mining, and other special schools. In 1913 there were 15,586 elementary schools, with 21,234 teachers and 899,850 pupils. Among the recruits of 1910 only 0.23 per cent were unlettered, only 0.43 per cent unable to write. In 1913 the expenditure on elementary education was 47,220,500 kronor, of which about one-fourth came from the national treasury.

**Ethnology.** The Swedes belong to the Scandinavian branch of the Teutonic stock. Their average stature is 1.705 metres, classing them among the tall races; the average cephalic index is 78.2. The Swedes are blonds, sturdy and robust. Prehistoric culture came from the south. In the settlement of Sweden the Goths or Gotar were the first conquerors of whom history tells. They occupied the southern parts, and following them came the Svear, who overran the rest of the country and gave their name to the Svenskar or Swedes of to-day. The Dalecarlians are thought to preserve best the type of the Svear; they are described as tall, slender, and

agile, with blue eyes and broad, open brow, courteous, cheerful, and firm, and with a wide reputation for honesty.

**History.** Tacitus in the *Germania* tells of the two great Germanic tribes in the Scandinavian peninsula, the Suiones or Swedes in the north, and the Gothones or Goths in the south. These two, like other rival Germanic tribes, seem to have been generally at war with each other, and it was not until about the fourteenth century that the country was really organized and unified through the cessation of jealousy between the two sections. The ancient Swedish people had a bond of union in their religion and a common sanctuary at Upsala, which was the early centre of Swedish nationality. The history of Sweden previous to the tenth century is wrapped in obscurity. In the first half of the ninth century Ansgar (q.v.), a Frankish missionary, came to Sweden from Denmark and began the teaching of Christianity, which slowly became established in the country. Under Eric the Saint (1150-60) the Swedish power was strengthened and extended and Christianity with it. Churches were built and monasteries founded. Eric carried Christianity into Finland with the sword and established Swedish settlements in that country, whose subjugation, however, was not completed until more than a century after his death. He was defeated and killed in 1160 by the Danish Prince Magnus Henriksøn, who made an unprovoked attack upon Sweden, the beginning of a long series of wars between Sweden and Denmark, productive of national hatred and bitterness. The reigns of the early Swedish kings were short and stormy. In 1389 the Swedish nobles, disgusted with the conduct of their King, Albert of Mecklenburg, offered the crown to Margaret, Queen of Denmark and Norway, daughter of Valdemar IV, who defeated and dethroned Albert, and in 1397 brought about the union of Kalmar, by which the three Scandinavian kingdoms were henceforth to remain united under a single sovereign. This union continued with interruptions for more than a century, but with constant dissensions and wars between Denmark and the Swedish people. The Swedes themselves were divided between the upholders of national sovereignty and the supporters of the pretensions of the Danish kings. In the latter part of the fifteenth century the family of Sture (q.v.) rose to eminence in the struggle for national independence, Sten Sture the Elder being proclaimed administrator of the Kingdom in 1470. In 1520 Christian II of Denmark invaded Sweden to enforce his claim to sovereignty. The administrator, Sten Sture the Younger, was defeated and mortally wounded, and Christian entered Stockholm, where he enacted a carnival of blood, executing a large number of the nobles. Sweden soon rose against the tyrant (1521) under the lead of Gustavus (I) Vasa, who was made administrator. He shook off the hated yoke of Denmark and in 1523 became King of Sweden. About 1529 Lutheranism became established as the state religion of the Kingdom. Gustavus Vasa organized the Kingdom as a hereditary monarchy, in which the power of the nobles was circumscribed and that of the clergy subordinated to that of the state. He fostered trade, manufactures, art, learning, and science, and left a full exchequer, a standing army, and a well-appointed navy.

The great work of the first Vasa sovereign was almost undone by his son and successor, Eric

XIV (1560-68), who became insane and was deposed, being succeeded by his brother, John III. At the beginning of Eric's reign Esthonia, a fragment of the dominions of the Knights Swordbearers, submitted to Sweden. The reign of John III (1568-92) was notable for a reaction towards Catholicism. He had married Catharine Jagellon, of the Polish royal house, and in 1587 secured the election of his son Sigismund to the throne of Poland. For this Sigismund had to profess Catholicism. The great majority of the Swedes were strong Protestants, and when Sigismund succeeded his father as King of Sweden and attempted to restore Catholicism he was compelled by the Diet to resign the throne in 1599. His uncle Charles, the only one of Gustavus Vasa's sons who inherited his talents as a ruler, was made administrator of the Kingdom and in 1604 was crowned King as Charles IX. The policy of Charles IX was to encourage the burgher classes at the expense of the nobility; and by his successful efforts to foster trade—in furtherance of which he laid the foundations of Göteborg and other trading ports—to develop the mineral resources of the country, and to reorganize the system of Swedish jurisprudence, he did much to retrieve the calamitous errors of his predecessors. (See CHARLES IX.) The deposition of Sigismund gave rise to a long war with Poland. Charles was succeeded by his son, Gustavus (II) Adolphus (1611-32). This greatest of Swedish kings was confronted at the beginning of his reign by wars with Russia, Poland, and Denmark, which last-named power still owned Scania and other districts at the southern extremity of the Scandinavian peninsula. These wars were concluded advantageously for Sweden, which acquired Ingria, Karelia, and Livonia (the last named not formally renounced by Poland until 1660), and the King addressed himself to the task of making Sweden the dominant power on the Baltic. In 1630 Gustavus Adolphus came to the rescue of German Protestantism, which had succumbed to the arms of Tilly and Wallenstein. (For his victorious career in Germany, and the successes of the generals who were trained in his school, see the articles GUSTAVUS (II) ADOLPHUS and THIRTY YEARS' WAR.) The foreign policy of Gustavus Adolphus was continued after his death at Lützen in 1632 by his able Chancellor, Oxenstierna (q.v.), who directed the government during the minority of Gustavus' gifted but eccentric daughter Christina (1632-54). As a result Sweden was for nearly a century the great power of the North. By the Peace of Westphalia (1648) Sweden received Hither Pomerania (west of the Oder), the island of Rügen, and other territories in Germany, and was admitted to representation in the German Diet.

Charles X Gustavus (1654-60) waged a fierce war against the Polish King, John Casimir, in which the Swedish forces overran Poland. He conquered from Denmark the provinces of Scania, Halland, and Blekinge, which rounded out the Swedish boundaries. The war with Poland was closed at his death by the Peace of Oliva (1660). Misgovernment by a regency followed during the minority of Charles X's son and successor, Charles XI (q.v.) (1660-97). This King was involved as the ally of Louis XIV in European wars, which the regency had not left him the resources to carry on. In 1675 the Swedes suffered a great defeat at the hands of Frederick William, the "Great Elector" of Brandenburg,

at Fehrbellin. Charles XI reorganized the government and was declared an absolute sovereign by the Estates in 1693. His son, Charles XII (1697-1718), by his military genius raised Sweden to an extraordinary height of power. Not long after his accession he successfully met a joint attack by Russia, Poland, and Denmark, whom he dealt blows that astonished the world. His mordinate ambition, however, finally brought ruin upon Sweden. Peter the Great wrested Karelia, Ingria, Esthonia, and Livonia from Charles, who met his death in an invasion of Norway, leaving the Kingdom overwhelmed with debts and again disorganized. With him the male line of the house of Vasa expired. Upon the death of Charles XII the power of the crown was greatly limited by a new constitution ratified in 1720. Theoretically all power was vested in the Riksdag, or Diet, consisting of four distinct orders or estates—nobles, clergy, burgesses, and peasants sitting separately. The real power, however, was exercised by a "Secret Committee" consisting of 50 nobles, 25 clergy, and 25 burgesses, which prepared all bills for the Riksdag, created and deposed ministers, and controlled the foreign policy of the nation. The King presided over the sessions of the Senate, in which body he had a casting vote in case of a tie. The constitution made the King largely a figure-head in the government. Charles XII's sister, Ulrica Eleonora, who succeeded him, and her husband, Frederick of Hesse-Cassel, who shared the throne, were mere puppets of the nobles, whose dissensions as the factions of the Hats, or French party, and the Caps, or Russian party, brought on the country calamitous wars and almost equally disastrous treaties of peace. The weak Adolphus Frederick of Holstein-Gottorp, who was called to the throne on the death of Frederick in 1751 and died in 1771, did little to retrieve the evil fortunes of the state. (See STRUENSEE.) His son, Gustavus III (q.v.) (1771-92), skillfully availed himself of the general dissatisfaction of the people with the nobles to destroy the factions of the Hats and Caps, and under a new constitution to restore the power of the crown and of the popular estates at the expense of the nobles. His extravagance and dissoluteness detracted, however, from his merits as a ruler. He was assassinated in 1792. His son and successor, Gustavus IV Adolphus (q.v.), was but three years of age at his accession, and was forcibly deposed in 1809, and obliged to renounce the crown for himself and his direct heirs in favor of his uncle, Charles XIII (1809-18), who was compelled at once to conclude a humiliating peace with Russia, by the terms of which Finland was severed from Sweden. The early part of the reign of Charles, who was childless, was troubled by domestic and foreign intrigues concerning the choice of an heir to the throne. Finally, hoping to conciliate Napoleon, the dominant party in Sweden elected General Bernadotte to the rank of Crown Prince. Bernadotte led the Swedish forces in support of the allies against the French Emperor in 1813-14. With the aid of England, Sweden compelled Denmark, in January, 1814, to cede Norway to her, the Swedish possessions in Pomerania being handed over to Denmark. The Congress of Vienna (1814-15) recognized the union of Norway with Sweden; Swedish Pomerania passed to Prussia. In 1818 Bernadotte mounted the throne as Charles XIV John (q.v.). Under his able administration the united king-

doms of Sweden and Norway made great advances in material prosperity and political and intellectual progress; and although the nation at large entertained very little personal regard for their alien sovereign, his son and successor, Oscar I (1844-59), and his grandsons, Charles XV and Oscar II, who came to the throne in 1872, won a large share of the affections of the Swedes. The union with Norway, maintained in peace for many years, began to show signs of strain in the second half of the nineteenth century in proportion with the growth of Norwegian commerce and industry and of a national feeling. The union was dissolved, June, 1905, by the act of Norway. See NORWAY for an account.

During the reign of King Oscar II many important measures of social reform were adopted, including accident insurance for workmen, limitation of the working hours for women and children, and factory legislation.

In 1907 King Oscar II died and was succeeded by his son, Gustavus V. The question of the extension of the franchise which had been under consideration since 1900 was settled in 1909 by the passage of a bill establishing manhood suffrage for the elections to the Lower House, a reduction of the qualifications for eligibility to the Upper House, and a system of proportional representation for both Houses.

A cabinet crisis arose in Sweden early in 1914 due to a difference in the policies of the King and the Liberal ministry on the subject of defense. The King advocated the immediate strengthening of the military forces of the Kingdom, while the Liberals favored an appeal to the country on the question. Popular demonstration in support of the King led to the resignation of the Liberal ministry, and in the succeeding election the Liberals suffered greatly, gains being made by both the Conservatives and Socialists.

At the outbreak of the European War in 1914 Sweden declared her neutrality. Subsequently she entered into an agreement with Norway and Denmark to defend their neutrality and protect their economic interests. See WAR IN EUROPE.

**SWE'DENBORG**, *Swed. pron. svä'den-böry'*, EMANUEL (1688-1772). A Swedish scientist and theologian. He was born in Stockholm and died in London. He was educated at Upsala and traveled for four years in England, Holland, France, and Germany. On his return to Sweden he was appointed by Charles XII to an assessorship of mines. Swedenborg was ennobled in 1719, and the family name changed from Svedberg to Swedenborg. Swedenborg published short treatises on various topics in the fields of mathematics, astronomy, physics, and chemistry. He devoted himself for eleven years to the duties of his assessorship and to a systematic description of mining and smelting, and the construction of a theory of the origin of creation. The result appeared at Leipzig in 1734, in three massive folios, entitled *Opera Philosophica et Mineralia*, of which the first volume was called *Principia*. This was followed in the same year by a treatise on *The Infinite, and the Final Cause of Creation; and the Mechanism of the Operation of the Soul and the Body*, carrying the doctrine of the *Principia* into higher regions. Dissatisfied with his conclusions, he determined to track the soul to its inmost recesses in the body. His studies in human anatomy and physiology, with this end in view, appeared as *Economia Regni Animalis*, in two volumes (1741), and as *Regnum Animale*, in three volumes, unfinished (1744-45).

At this point his course as scientist was arrested and he entered on his career as seer, by which he is known in history. After 1745 he professed to have had his spiritual senses opened. His recorded experience was unique in that he did not claim to have communication with spirits, as does modern spiritualism, nor to

have visions merely, but he claimed to be himself consciously an inhabitant of the spiritual world as if he had died, and thence to be associating with the people of that world as one of them. In 1749 he made his first public appearance in his new character in the issue in London of the *Arcana Coelestia*, completed in 1756 in eight quartos. It is an exposition of the internal, or spiritual, sense of Genesis and Exodus. Adam signifies the most ancient church, and the flood its dissolution; Noah, the ancient church, which, falling into idolatry, was superseded by the Jewish. The spiritual sense pervades the Scriptures, with the exception of Ruth, Chronicles, Ezra, Nehemiah, Esther, Job, Proverbs, Ecclesiastes, the Song of Solomon, the Acts of the Apostles, and the Epistles. By reason of its symbolism of the inward sense, the letter of Scripture is holy in every jot and tittle. The Jewish dispensation having reached its period, God appeared in Jesus Christ. He assumed human nature in its lowest condition in the Virgin, wrought it into conformity with himself, "glorified and made it divine." There is a Trinity, not of persons, but of divine essentials, consisting of the Father, or God as He is in Himself, and thus incomprehensible to man; the Son, or God as revealed to man in Jesus Christ; and the Holy Spirit, or divine operation thence. It is imaged in man by his soul, his body, and their operation. The Church which Christ established at his advent in the flesh came to an end in 1757. Then commenced a new dispensation and a new church, signified by the New Jerusalem in the Revelation, of which church the writings of Swedenborg contained the doctrines.

The distinctive principle of Swedenborgian theology, next to the doctrine of the divine humanity, is the doctrine of life. God alone lives. Creation is dead—man is dead; and their apparent life is the divine presence. God is everywhere the same. It fallaciously appears as if He were different in one man and in another. The difference is in the recipients; by one He is not received in the same degree as another. There is an inmost or highest degree or plane of man's reception of the divine life, called the celestial or love plane; there is a second or lower degree of receptivity, called the spiritual or wisdom plane, and there is a third, called the natural or plane of obedience. The life of evil is the perversion of divine life into disorderly forms. These degrees of man's reception of God's life are entirely separate from each other and can never be commingled. They are related by correspondence, by which each lower degree derives its existence and its life from the plane above. The relation of correspondence is complete, there being nothing in a higher plane which is not represented by something corresponding to it in the plane below; and there is nothing in the lower plane which does not exist from some corresponding thing in the plane above; and all this to the most minute detail, even to the things on this earth. Earthly things beautiful and useful manifest spiritual good; and earthly things ugly and hurtful, spiritual evil. The Scriptures are written according to correspondences, and by the aid of that science their mysteries are unlocked. By it, too, the constitution of heaven and of hell is revealed. There are three heavens in which there live three orders of angels, the natural, the spiritual, and the celestial; they are three

planes or degrees of man's receptivity of divine life described above. All angels were once men, and have lived on this or some other planet. They marry and live in societies, in cities and countries as in the world, in outer appearance differing only in the vast superiority and glory of these things there. But the similarity between the life of angels in heaven and that of men on earth is of the outer appearance only, while the differences between them are internal and radical; for it is not in degrees of outer perfection and glory that the life in heaven and the life on earth may be compared truly, but in their capacity to supply a field for the realization of the inner life of the soul. To the angels the images presented to their senses are the expressions of ideas and emotions which are by this means revealed to them; and so concerned are they in these meanings, that they are unconscious of the objects of their senses, or of their own bodily life, as such. To them their sense life therefore is made only a concrete spiritual life. There is no denominational favoritism with God; all in whom the love for God and man prevails in any degree whatever, irrespective of their church or religious connection, go to heaven after the death of their bodies. Between heaven and hell there is an intermediate state called the world of spirits, where all those who pass into the spiritual world are prepared for their final states. Hell is not merely a place of punishment for the sins done in the body, but is a provision of divine love, and the necessary state and condition of the unregenerated natural man. No one is sent there, but the unregenerated seek a place there of their own accord. Hell as a whole is called the devil, or Satan; there is no supreme individual bearing that name. There are three hells opposite the three heavens.

**Bibliography.** Complete editions of Swedenborg's writings have been issued in English by the Swedenborg Society of London, which has also issued a concordance to the works by J. F. Potts (6 vols., London, 1888 et seq.). There is also the *Rotch Edition* (32 vols., Boston, 1907); separate works have been issued in various editions, among them being *The Animal Kingdom* (Philadelphia, 1912), and *Divine Providence*, and *Divine Love and Wisdom*, in Everyman's Library (New York, 1913). Numerous biographies have been written, among them being: J. J. G. Wilkinson, *Emanuel Swedenborg: A Biography* (Boston, 1849); E. A. Hitchcock, *Swedenborg: A Hermetic Philosopher* (New York, 1858); William White, *Emanuel Swedenborg: His Life and Writings* (2 vols., London, 1867); Benjamin Worcester, *Life and Mission of Emanuel Swedenborg* (5th ed., Boston, 1901); id., *Swedenborg: Harbinger of the New Age* (Philadelphia, 1910); R. W. Emerson, "Swedenborg, or the Mystic," in *Representative Men* (Centenary ed., Boston, 1903); George Trobridge, *Life of Emanuel Swedenborg* (ib., 1913); Pauline Bernheim, *Balzac und Swedenborg* (Berlin, 1914); also *Documents Concerning the Life and Character of Emanuel Swedenborg, Collected, Translated, and Annotated* by R. L. Tafel (3 vols., London, 1875-77), a very scholarly work, compiled with great labor; J. J. G. Hyde, *Biography of the Works of Emanuel Swedenborg* (New York, 1906); A. H. Stroh, *Abridged Chronological List of the Works of Emmanuel Swedenborg* (Upsala, 1910). A sumptuous edition of his scientific works is being issued under the

auspices of the Swedish Royal Academy of Sciences. Many volumes of his manuscripts have been reproduced in photolithograph and photo-type.

**SWEDENBORGIANS**, swē'den-bōr'jī-anz. The name popularly applied to those who accept the doctrines of Christianity and of philosophy as set forth in the writings of Emanuel Swedenborg (q.v.). They do not call themselves Swedenborgians, but members of the New Church. Swedenborg formed no ecclesiastical organization, but declared that in time there will exist a universal new church, which is prefigured by the New Jerusalem of the Apocalypse (Rev. xxi). Many followers of Swedenborg do not sever themselves from their previous church connections; but a number have organized a church to which they give the name New Church or New Jerusalem. It is only these whose numbers and work can be definitely reported. The first movement towards organization began in Great Britain in 1782, when Robert Hindmarsh, a printer of London, and certain associates formed a class for reading and studying the writings of Swedenborg. This grew into a society for worship and preaching. Public services were first held in 1788. The General Conference of the New Jerusalem Church in that country began its sessions in 1789, and since 1815 has met annually. In 1915 the conference consisted of 72 societies, with an aggregate membership of 6694 with 46 ministers. There are also a number of societies not connected with the conference and many isolated members not reported in these statistics. There are probably 10,000 followers of Swedenborg in Great Britain and Ireland. On the continent of Europe there are societies of New Churchmen in Paris, Zurich, Berlin, Budapest, Vienna, Stuttgart, Copenhagen, and in Stockholm, and many individual followers of Swedenborg in every country of Europe. In the United States the first society of the New Church was organized in Baltimore in 1792. The General Convention of the New Jerusalem in the United States and Canada held its first meeting in Philadelphia in 1817. With four exceptions this body has held annual sessions ever since. In the United States societies are grouped into State organizations called associations. The General Convention is composed of 12 of these associations and of seven separate societies. The individual membership of the bodies composing the convention, as reported in 1915, is 6363, with 103 ministers and 96 societies. In addition to these there are many scattered receivers of Swedenborg's doctrines who are not members of the organization. There is a smaller organization of the Swedenborgians called the General Church of the New Jerusalem. Its headquarters are in the United States, though it has members in other countries. It is an offshoot from the convention, having withdrawn from that body in 1891. In 1915 it reported a membership of 1213 persons with 34 ministers. In Australia, New Zealand, Cape Province, Natal, Transvaal, Mauritius, India, British Guiana, Mexico, and Brazil, there are societies and scattered receivers of Swedenborg's doctrines, and individual members in all parts of the globe. Taken all together there are about 20,000 members of the faith in the world.

The ministry of the New Church is patterned after the Episcopal order; but there is in reality a practical congregationalism. Originating in isolated places, the societies managed their

own affairs, selected their own ministers, and joined with other societies largely for coöperative missionary work. The ministers and churches of the countries outside Great Britain and the United States, although practically independent, are closely connected with the three general bodies already mentioned, both by close association and coöperation, and by assistance rendered to the relatively weak brethren scattered throughout the world.

There are three institutions at which the ministers are educated. The English Conference has a theological school in London, the New Church College. The General Convention's theological school is in Cambridge, Mass., and the Academy of the New Church located at Bryn Athyn, Pa., has a theological school at which the ministers of the General Church of the New Jerusalem are educated. The three general bodies also carry on the work of general education in a number of schools in America and Great Britain.

The organizations of the New Church have been active in printing and publishing. The works of Swedenborg have been issued in whole or in part in many different languages and in many editions. Many periodicals have been published, some of them continuing through more than a century. For bibliography, see SWEDENBORG, EMANUEL.

**SWEDISH LANGUAGE AND LITERATURE.** Swedish belongs to the northern branch of the Germanic family, within which it is an eastern development of the old *Donsk tunga*, or Danish tongue, a name anciently applied to the language spoken not in Denmark only, but in the rest of Scandinavia. It was much the same in the entire Northland down to about 900 A.D., when it began to differentiate into an eastern type, ramifying into Danish and Swedish, and a western type, producing Norwegian and Icelandic. From 900 to 1500 the Swedish branch is called Old Swedish. Until after 1200 the only records are runic inscriptions, cut chiefly on gravestones. Use of the Latin alphabet began in the thirteenth century. In the fourteenth century, when a literary language began to develop out of the Södermanland dialect, differentiation from Danish proceeded slowly; then came a period of approximation to Danish, followed in time by an archaizing period, restoring original forms. Aside from divergences of vocabulary, Swedish now differs from Danish especially in its retention, after a vowel, of the old voiceless consonants, *k, t, p*, which in Danish changed to *g, d, b*, and in its retention of the vowels *a* and *o* in unstressed syllables, where Danish has *e* or no vowel; thus, Swedish *bok*, book, *mat*, meat, *apa*, ape, are in Danish *bog*, *mad*, *abc*. Swedish *talar Ni svenska* (do you speak Swedish?) is in Danish *taler De svensk*; and Swedish *flickan liknar sin mor* (the girl resembles her mother) is in Danish *Pigen ligner sin Moder*. Under this head it may be added that Swedish has not the "glottal catch" of Danish, and Danish has not the modulated musical accent of Swedish.

The main body of the Swedish vocabulary is old Germanic stock, the principal foreign ingredients being (1) Latin and Greek words that came with Christianity or with the growth of scholarship; (2) Low German words dating from the time of the Hanseatic League, as *arbete*, to work, *stövel*, boot, *smaka*, taste; (3) German words from about 1620, as *tapper*,

*duva*, *prakt*, splendor; (4) French words borrowed in the seventeenth and eighteenth centuries, as *affär*, business, *talang*, talent, *charmant*, charming. Like other North Germanic tongues, Swedish has the postpositive definite article (originally a pronominal affix); thus, *flicka*, girl, *flickan*, the girl. As in English, nouns have but one case (the genitive or possessive), now distinguished by inflection. The genitive ending is *-s*, which is appended after the article; thus, *flickans mor*, the girl's mother. The plural of nouns is formed by means of the endings *-or*, *-ar*, *-er*, *-en*, to which the definite article is appended in the forms *-na*, *-ne*, according to a feeling for vowel balance which began about the fourteenth century; thus, *flickorna*, the girls, but *dalarne*, the dales. A new pronoun of address, *ni*, taking the place of *I*, came in the seventeenth century and is now commonly used in books; but in conversation Swedish politeness avoids it and substitutes the title of the person addressed, putting the verb in the third person; thus, *är frun sjuk*, is the lady sick? = are you sick, madam? The verb still retains the old Scandinavian passive in *-s*, originally an affixed reflexive pronoun; thus, *kalla*, call, *kallas*, to be called. A peculiar feature of conjugation is the differentiation of the perfect passive participle into two forms, one of which, called the supine, is used to inflect the perfect tenses, while the other is declinable and serves as a true participle; thus, *jag har älskat*, I have loved, but *jag är älskad*, I am loved, and *vi äro älskade*, we are loved.

In the printing of Swedish Roman letters have long prevailed. The written language of to-day represents nearly the pronunciation of about 200 years ago; and as phonetic change has been at work during the interval, it is the case, as in English, that the written form is often a poor index to colloquial utterance. Swedish print teems with silent letters; thus, *jag skal vara i staden* (I shall be in the city) is pronounced *ja ska vara i stän*; and *hvad är det* (what is it?) becomes *va ä de*. For the learner of Swedish a great difficulty comes from its peculiar accent, which involves both stress and variations of musical pitch. Every word has either the simple or the compound tone. The simple tone is a rising modulation, while the compound "consists of a falling tone on the stress syllable, with an upward leap of the voice and a slight secondary stress on a succeeding syllable." (Sweet.) Not only pronunciation, but meaning, often depends on the exact modulation of a word's musical accent.

**Literature.** About 160 of the runic inscriptions of Sweden, the oldest dating from the tenth century, contain alliterating verses evidently quoted from preëxisting sagas. This and other lines of evidence show that the poetic art was widely cultivated in the Viking age. But this literature, perhaps comparable to that preserved in Old Icelandic, is lost. By the middle of the twelfth century Christianity was firmly established, and old pagan songs and sagas were banned by the Church. For five hundred years afterward national literature was dominated, more than elsewhere in western Europe, by the religious spirit. The earliest writings handed down in the Latin alphabet are codes of provincial laws (*landskapslagar*), the most important the "Elder West Göta Law" (thirteenth century). Magnus Eriksson's *Landslag* (about 1350) is that King's attempt to provide a com-

mon law for all the provinces under his rule. It was probably a scholar from his entourage who wrote the celebrated *Um styrlisi konunga ok höfðinga* (On the Conduct of Kings and Magnates). To the fourteenth century belong writings (nine books of Revelations) ascribed to St. Birgitta, a nun and mystic revealer of heavenly things. She is the most eminent personage in the annals of Catholic Sweden. Her convent at Vadstena became a literary centre, where Latin writings, mystical and hagiographic, but including also a part of the Bible, were translated into Swedish for the nuns. In poetry the mediæval period is not very rich, though its metrical production is considerable. Romances of chivalry are the so-called *Eufemiavisor*, certain tales of knightlood done into Swedish verse by a gleeman at the court of Queen Euphemia of Norway (1303-12). They are *Herra Iwan*, *Hertig Fredrik af Normandic*, and *Flores och Blanzeflor*, all in rhyming couplets with four accents to the line. Besides these there are several rhymed chronicles, the oldest being the *Erikskrönika* (about 1320), the *Chronica Gothorum* (1470) by Ericus Olai, and the ballads. The ballad-making period in Sweden was chiefly in the thirteenth and fourteenth centuries, but the extant collections are of the sixteenth and seventeenth. No well-known ballads are of indisputable antiquity, but the best compare well in form and matter with the better *Kæmpeviser* of Denmark. From the fifteenth century we have a few good poems by Bishop Thomas of Strengnäs (died 1443).

The Reformation transferred the literary centre from Vadstena to Upsala. The literature of the sixteenth century is nearly all religious, the chief writers being the brothers Petri, Carmelite monks who had been converted to Lutheranism at Wittenberg. They stand out as leading Swedish apostles of the new faith. The elder, Olavus (Mäster Olof), wrote psalms, devotional poems, a prose chronicle of Swedish history, and (probably) the mystery play *Tobias Comædia*. With his brother Laurentius he directed the publication of the first Swedish Bible (Upsala, 1541). The first secular author of any note in the new era is the historian Messenius, who also wrote six "school comedies" on subjects from Swedish history. The best known is *Disa*, which was played by Upsala students in 1611.

The period of Swedish expansion (1630-1730) is marked by the widening of the literary horizon through the introduction of new ideas and forms from Germany, France, Italy, and Holland. The prominent figure is Stiernhielm (1598-1672), the father of Swedish poetry. His work was like that of Opitz in Germany, who influenced him. His poem *Hercules*, a didactic allegory on the conflict of Pleasure and Duty, may fairly be said to have nationalized the dactylic hexameter. Stiernhielm also produced sonnets and ballads. His most noteworthy disciple was the poet-scholar Columbus (1642-79). An opponent of Stiernhielm, Rosenhane (1619-84), won fame as a sonneteer. A facile, original rhymester was Johansson, called *Lucidor* (died 1684). The eccentric polyhistor Rudbeck (1630-1702), with his amazing *Atlantika*, belongs to the history of literary curiosities rather than of literature.

In the ensuing epoch (1730-72) the great Swedish names are Swedenborg (1688-1772) and Linnæus (1707-78), belonging respectively to religion and science. In belles-lettres the

ideals of Sweden were substantially those of contemporary France and England. The presiding genius is Dalin (1708-63), whose *Swedish Argus*, started in 1733 in imitation of the *Spectator*, became the rallying point of the dominant ideas. Dalin wrote much poetry, but is best remembered as an elegant stylist in prose, the first in Swedish annals. Opposed to Dalin in some of his tendencies was the coterie of Fru Nordenflycht (1718-63), the Northern Aspasia. To her circle belonged Creutz (1731-85), best known for his pleasant pastoral *Atis och Camilla*, and Gyllenberg (1731-1808), author of ratiocinative poems. All these midcentury writers were strongly influenced by contemporaries in England.

The Gustavian epoch (1772-1809) is marked by royal patronage of letters. Gustavus III, himself a playwright and a prize orator, assembled an academic court of talent, similar to the French Old Régime. Leading Gustavians were Kellgren (1751-95), Leopold (1756-1829), and Oxenstierna (1750-1818), all poets of talent and devoted to the ideals and sentiments of their day. Here belongs also the name of the gifted poetess Fru Lenngren (1754-1817), famed for her idyls and satires and her literary salon. Quite untouched by academic influence was the much-admired Bellman (1740-95), a genial humorist of Anacreontic tendencies, who turned his observations of Stockholm low life into tuneful verse. To the Gustavian period belongs (though somewhat of a new era) the best work of the eminent lyric poet Franzén (1772-1847).

The great Romantic movement of the nineteenth century, with its renaissance of national feeling, affected Swedish literature profoundly. New ideas, coming from Germany by way of Denmark, precipitated at first a conflict of schools and tendencies, after which came a season of brilliant production. In the soulful verse of Wallin (1779-1839); in the best work of the arch-Romanticist Atterbom (1790-1855); in the fine spirituality and exquisite workmanship of Stagnelius (1793-1823); in the stirring Northern poems of Geijer (1783-1847), destined to become, next to Fryxell, perhaps, his country's greatest historian; in the productions of the brilliantly endowed but erratic Almqvist (1793-1866); and of minor poets like Sjöberg (1794-1828) and Njander (1799-1839); but above all in the splendid talent of Tegnér (1782-1846), famed for his romanticized *Frithiof's Saga*—the national genius found a richer expression than at any time before or since.

In the midcentury period the prominent names are Fredrika Bremer (1801-65), once widely read at home and abroad, and Runeberg (1804-77), a rival of Tegnér for the first place of honor in the whole Swedish Parnassus. Somewhat later come Topelius (1818-98), best known for his novels of Finnish history, and Rydberg (1828-95), eminent as poet, novelist, and translator of Goethe's *Faust*, and the poet Count Snoilsky (1841-1903). The new realism is most conspicuously represented by Strindberg (1849-1912), the greatest author of his day and country, remarkable alike for the quality, variety, and mass of his work; by Anne C. Leffler (1849-92); and by Geijerstam (1859-1909). Opposition to realism is represented by Heidenstam (1859- ), Levertin (1862-1906), and the spirited romanticist Selma Lagerlöf (1858- ), a winner of the Nobel prize. Late writers who belong to no special school are the

poet Fröding (1860-1911), a skilled metrician, the poet Karlfeldt (1864- ), and the story writer Hallström (1866- ).

**Bibliography.** Language: For Old Swedish the leading authority is A. G. Noreen, *Alt-schwedische Grammatik* (Halle, 1897; new ed., ib., 1904). He has also treated the subject in his *Geschichte der nordischen Sprachen* (Strassburg, 1898), a reprint of his article in Hermann Paul, *Grundriss der germanischen Philologie* (2d ed., Strassburg, 1898). A good work on Swedish grammar is Rydqvist, *Svenska språkets lagar* (6 vols., Stockholm, 1850-83). A small grammar is Schwarz and Noreen's *Svenska språklära* (ib., 1881). The great work is by A. G. Noreen, *Vårt språk* (Our Language) (ib., 1903 et seq.; to constitute nine volumes). Grammar in English is E. J. Vickner, *A Brief Swedish Grammar* (Rock Island, Ill., 1912; rev. ed., 1914). The best Swedish-English dictionary is that of Björkman (Stockholm, 1889), and English-Swedish is that of Wendström and Lindgren (ib., 1889). The great dictionary of the Swedish Academy, *Ordbok öfver svenska språket* (Lund, 1898 et seq.; 3 vols. ready in 1915) is not far advanced. For dialects consult Lundell, *Nyare bidrag till kännedom om de svenska landsmålen*, etc. (Stockholm, 1879 et seq.). An excellent account of Swedish pronunciation by Sweet is given in *Transactions of the Philological Society* (London, 1877-79); also L. Marshall (ed.), *Swedish-American Handbook* (Philadelphia, 1914). Literature: A good anthology of Old Swedish will be found in Noreen's *Alt-schwedisches Lesebuch* (Halle, 1892-94), and of the entire literature (to 1830) in the *Läsebok i svensk litteratur* of Hildebrand, Bergstadt, and Bendixson (Stockholm, 1897-98). The old laws have been edited by Schlyter, much of the religious mediæval literature by Klemming. Of older works on the history of literature the best are Oscar Wieselgren, *Sveriges skona litteratur* (Lund, 1833-49); and Malmström, *Grunddragen af svenska vittorhetens historia* (Örebro, 1866-69). The best work up to date is the *Illustrerad Svensk Litteraturhistoria* of Schück and Warburg (2 vols., Stockholm, 1896-97; 2d ed., 5 vols., ib., 1912-16). Consult also V. Palmgren, "Selected List of Swedish Books Recommended for Public Libraries," in American Library Association, *Foreign Book List*, No. 5 (Chicago, 1909); A. B. Benson, *Old Norse Element in Swedish Romanticism* (New York, 1914). See also references to articles on the individual authors mentioned.

**SWEDISH MOVEMENT.** See MECHANOTHERAPY.

**SWEDISH MUSIC.** See SCANDINAVIAN MUSIC.

**SWEDISH NIGHTINGALE.** A popular name given to the Swedish singer Jenny Lind.

**SWEDISH POLITICAL PARTIES.** See POLITICAL PARTIES.

**SWEELINCK**, swā'linp, JAN PIETERS (1562-1621). A Dutch organist and composer, born at Deventer or Amsterdam. He studied with Zarlino at Venice, and in 1580 succeeded his father as organist of the Old Church at Amsterdam, which position he held till his death. Through his pupils and organ works he exerted a far-reaching influence, being, in fact, the real founder of the great school of German organists which flourished during the seventeenth century. (See MUSIC, HISTORY OF, X.) It was he that originated the organ fugue

(see FUGUE) built upon a single subject to which countersubjects were gradually added. Of subsequent masters none equaled him until the mighty Bach appeared, Bach bringing this form of the fugue to perfection. Besides the organ works, upon which his importance chiefly rests, he set to music all the Psalms of David in four books (4-8 voices) and wrote *Rimes françoises et italiennes* and *Cantiones Sacrae cum basso continuo ad organum*. A complete edition of his works, in 12 volumes, edited by Max Seifert under the auspices of the *Vereeniging voor Noord-Nederlands Muziekgeschiedenis*, was published by Breitkopf and Härtel in Leipzig (1895-1903). Consult F. H. J. Tiedeman, *Jan Pieters Sweelinck, een bio-bibliografische Scheets* (Amsterdam, 1892).

**SWEENEY, THOMAS WILLIAM** (1820-92). An American soldier, born at Cork, Ireland. He went to the United States in 1832; in 1846 enlisted as second lieutenant in Burnett's New York Volunteers, and fought under General Scott in Mexico. At the outbreak of the Civil War he was in command of the arsenal at St. Louis, Mo. In reply to efforts of Confederate sympathizers to induce him to surrender that important post, he declared that before he would do so he would blow it up. As second in command he participated in the capture of Camp Jackson in May, 1861; assisted in organizing the Home Guards, and was chosen brigadier general of that organization, and commanded the Fifty-second Illinois at Fort Donelson. At Shiloh he successfully defended a gap in the Union line. He commanded the second division of the Sixteenth Army Corps in the Atlanta campaign. In 1866 he took a prominent part in the Fenian invasion of Canada. He retired from the army in 1870 with the rank of brigadier general.

**SWEET, BENJAMIN JEFFREY** (1832-74). An American soldier, born at Kirkland, Oneida Co., N. Y. At the age of 16 he moved with his father to Wisconsin. At the outbreak of the Civil War he helped to raise two regiments, and became colonel of one of them, the Twenty-first Wisconsin. At the battle of Perryville he received a wound that incapacitated him from further service in the field. In the spring of 1864 he was put in command of Camp Douglas at Chicago. In the following July and again in November he defeated plots of the Knights of the Golden Circle (q.v.) to capture Chicago and release the 10,000 Confederate prisoners confined in Camp Douglas. For these services he was promoted brigadier general of volunteers. From 1869 till 1870 he was United States pension agent at Chicago, and from 1870 till his death was First Deputy Commissioner of Internal Revenue at Washington.

**SWEET, HENRY** (1845-1912). An English philologist, born in London. He was educated at King's College, London, at Heidelberg, and at Balliol College, Oxford. He devoted himself principally to Anglo-Saxon and phonetics. He was the founder and leading spirit of the English school of phonetics, and his influence was such that the teaching of English pronunciation in Germany is based almost entirely on his work. He also made researches into Arabic and Chinese, and on the science of language in all its aspects he was a profound and original thinker. From 1901 until his death he was University Reader in Phonetics at Oxford. Of his editions of Anglo-Saxon texts the most important are King Alfred's version of Gregory's

*Cura Pastoralis* (1871); *Anglo-Saxon Reader* (7th ed., 1894); *Anglo-Saxon Primer* (3d ed., 1884); *Alfred's Translation of Orosius* (1883); *Epinal Glossary* (1883); *Oldest English Texts* (1885); *Student's Dictionary of Anglo-Saxon* (1897). Among his contributions to Anglo-Saxon philology are his *Dialects and Prehistoric Forms of Old English* (1876), and *A Sketch of Anglo-Saxon Poetry*, in Wharton's *History of English Poetry*, vol. iv (London, 1871). His work in phonetics includes his *Handbook of Phonetics* (1877); *History of English Sounds* (2d ed., 1888); *Primer of Phonetics* (1890; 3d ed., 1906); *Sounds of English* (1908). He is likewise the author of *Words, Logic, and Grammar* (1876); *Elementarbuch des gesprochenen Englisch* (2d ed., 1886); *New English Grammar* (1898-1900); *Current Shorthand, Orthographic and Phonetic* (1892); a literary study on *Shelley's Nature-Poetry* (1891); primers of Middle English (1884-86) and of Icelandic (1886); *The Practical Study of Languages* (1900); *The History of Language* (1900).

**SWEET, JOHN** EASON (1832-1916). An American engine builder, born at Pompey, N. Y. He was a builder and architect in the South until 1861, and was then engaged as an inventor and mechanical draftsman until 1873. In 1873-79 he served as professor of practical mechanics at Cornell. After 1880 he was president of the Straight Line Engine Company at Syracuse, N. Y. He was president of the American Society of Mechanical Engineers (1884), which awarded him the John Fritz medal in 1914; of the Engine Builders' Association of the United States (1899-1901); and of the Syracuse Metal Trades Association (1906-07). He published *Things that Are Usually Wrong* (1906).

**SWEETBRIER.** See EGLANTINE.

**SWEET CALABASH.** See GRANADILLA.

**SWEET CICELY.** See CHERVIL.

**SWEET CLOVER.** See MELILOTUS.

**SWEET CORN.** See MAIZE.

**SWEET FERN.** A popular name for *Myrica asplenifolia* and *Myrrhis odorata*, also known as sweet cicely, both of which have fernlike foliage. The former, being rich in tannin, has been employed as an astringent in domestic medicine; the latter is employed in cooking, for its agreeable flavor.

**SWEET FLAG.** See ACORUS.

**SWEET GALE.** See CANDLEBERRY.

**SWEET GUM.** See LIQUIDAMBAR.

**SWEET OIL.** See OLIVE OIL.

**SWEET PEA** (*Lathyrus odoratus*). An old-fashioned papilionaceous garden flower brought into prominence and greatly improved in form and color late in the nineteenth century. The plant is a free random grower like other peas, but has perfumed flowers of greater beauty. Sweet peas should be planted as early in spring as the ground can be worked. Rich, deeply prepared clay loam is best. Thin, dry soils are not satisfactory. The seed should be sown thinly, 2 to 3 inches deep in trenches 4 to 5 inches broad and as deep, 3 to 3½ feet apart. Brush or trellis should be provided when the plants are 2 inches high, and shallow cultivation given through the growing season and blooming period, gradually filling the trench. No pods should be allowed to ripen as long as flowers are wanted; growth ceases with this ripening. Several hundred named varieties are in cultivation, including nearly a hundred winter-flowering varieties for the forcing house. Two

other closely related peas are also cultivated for their flowers—the sweet tangier pea (*Lathyrus tingitanus*) and the perennial or everlasting pea (*Lathyrus latifolius*). Both have long been in cultivation in Europe. The latter, which is very hardy, has many-flowered clusters, large standard scentless flowers, strongly veined leaflets, and broad, hairless pods. There are several dis-

SWEET PEA (*Spencer variety*).

eases of sweet peas that are quite destructive at times. The disease called streak in England is now known to be due to *Bacillus lathyri*, a species of bacteria, which also attacks clovers, garden beans, etc. *Fusarium lathyri* attacks the roots and *Sclerotinia libertiana* causes a collar rot of sweet peas. *Glomerella rufomaculans*, the cause of the bitter rot of apples, also causes an anthracnose of sweet peas. Seed and soil treatment with fungicides (q.v.) and planting resistant strains where any are known are suggested as methods of prevention. Consult: T. Stevenson, *The Modern Culture of Sweet Peas* (London, 1911); G. W. Kerr, *Sweet Peas up to Date* (Philadelphia, 1914); "Sweet Pea Studies," in Cornell Agricultural Experiment Station, *Bulletins* 301, 319, 320, 342 (Ithaca, N. Y.). See LATHYRUS.

**SWEET POTATO, or BATATAS** (*Ipomoea batatas*). A perennial plant of the family *Convolvulaceae*, with long creeping stems, heart-shaped leaves on long stalks, and variously lobed large purple flowers resembling those of the best-known species of *Convolvulus*, and large oblong or elongated roots. Authorities differ as to its origin (East India or America), but it is now cultivated in all tropical and subtropical countries for its sweet, wholesome roots, which are highly esteemed as an article of food. In the United States the sweet potato thrives best in the South Atlantic and Gulf coast States, but may be grown for home use as far north as southern New York. It is grown in the central valleys of California, but does not do well in dry arid regions and where the nights are cool during the growing season.

The sweet potato is propagated by sets obtained from the tubers sprouted in a specially prepared bed and when about 4 inches tall planted 18 inches apart in rows  $3\frac{1}{2}$  feet apart

in the field; the later vine cuttings, commonly used in the Gulf States and as far north as Virginia, require from 90 to 105 days to mature their roots. The crop grows best in a warm, sandy, well-drained soil. It requires clean cultivation. Early digging yields only one-half to two-thirds as much as may be obtained from the matured crop, which averages from 250 to 275 bushels per acre. The quantity and quality of the crop decrease as the northern limit of culture is approached. The roots should be harvested before frost and when the ground is dry. The roots must be stored in a rather warm, dry place, as otherwise heavy losses from rotting occur. The so-called "yams" grown in the United States are all sweet potatoes.

The most serious diseases of the sweet potato destroy the fleshy roots. The black rot (*Sphaeromecma fimbriatum*), which appears as greenish-black irregular spots which increase in size and eventually destroy the whole root, may be spread by diseased tubers in the seed bed or through fungus in the soil. At the New Jersey Experiment Station sulphur in the soil has been used with success as a preventive. Dry rot (*Diaporthe batatas*) dries, wrinkles, and fills the roots with powder. It attacks the whole root in the field. Vine wilt, yellows or stem rot, are caused by species of *Fusarium*, and it is often difficult to get a stand of sweet potatoes on account of the destruction of the young plants by these fungi. Soil rot (*Peronospora batatas*) is often destructive of sweet potatoes in the field. Nearly all the above diseases are spread through seed tubers, slips and seed beds, hence treating tubers with fungicides and attention to sterilizing seed beds is advocated. Rotation of crops and destruction of diseased material are recommended as preventatives. There are several storage rots of the sweet potato. A soft rot (*Rhizopus nigricans*) attacks stored roots, usually commencing at places where the skin has been broken. Other rots, more or less characterized by blackening, are due to *Trichoderma koningi*, *Sclerotium bataticola*, and *Diplodia tubericola*. Since moisture favors their spread, sweet potatoes should be stored in well-ventilated, dry rooms. A leaf spot (*Septoria bataticola*) often attacks and turns the foliage white, and a leaf mold (*Cystopus ipomoea-panduranae*) turns the leaves, especially the older ones, brown. Spraying with Bordeaux mixture or other fungicide (q.v.) is recommended for these last two and the first disease.

As ordinarily prepared for the table the skin constitutes on an average 20 per cent and the edible portion 80 per cent of the root. The edible portion has the following percentage composition: water, 69.0; protein, 1.8; fat, 0.7; nitrogen-free extract, 27.4; and ash, 1.1 per cent, the fuel value being 570 calories per pound. Sweet potatoes are a succulent food, the chief nutrient being carbohydrates, the principal of which is starch. Sugars are also found, 2.5 per cent cane sugar and 3.4 per cent invert sugar being the average amount found in a large number of analyses. In addition to the quantities consumed in the fresh state, sweet potatoes are also canned and evaporated. They are sometimes fed to farm animals, especially pigs. To secure the greatest profit the pigs should harvest the crop and some nitrogenous feed like cow-peas should also be fed. Consult: L. H. Bailey, *Cyclopedia of Agriculture* (New York, 1907); Beattie, "Sweet Potatoes," in United States

Department of Agriculture, *Farmers' Bulletin* No. 324 (Washington, 1908); H. C. Thompson, "Storing and Marketing Sweet Potatoes," in United States Department of Agriculture, *Farmers' Bulletin* No. 548 (Washington, 1913); J. G. Nordin, *The Sweet Potato: How to Grow and Keep it* (Russellville, Ark., 1912). See Plate of YAM, SWEET POTATO, etc.

**SWEET-POTATO INSECTS.** The leaves of the sweet potato are punctured by a small bronzed flea beetle (*Chatocnema confinis*), which eats channels along the veins soon after the plants have been set out and causes the leaves to shrivel. The most serious of the insect enemies of the crop are several species of tortoise beetles. (See TORTOISE BEETLE.) Among the commonest species are the two-striped tortoise beetle (*Cassida divittata*), which is pale yellow and has two black stripes on each wing cover. The larva is dirty yellowish white and covers itself with cast skins and excrement. It gnaws irregular holes in the leaves underneath which it transforms to pupa. The golden tortoise beetle (*Coptocycla aurichalca*), which is more abundant, resembles gold tinsel and is beautifully resplendent. The larva is dark brown and feeds like the previous species. Arsenical sprays have been recommended.

**SWEET-SCENTED GRASS.** See HOLY GRASS.

**SWEET-SCENTED SHRUB.** See CALYCANTHUS.

**SWEEP SOP** (*Annona squamosa*). A small deciduous tree of the family Annonaceae, a native of tropical America and introduced in other warm countries. The scaly greenish fruit has a soft, somewhat mealy, sweet, and luscious pulp with a musky aromatic odor and flavor. It is much used, generally raw, but sometimes cooked. Other species of *Annona* yield edible fruits, as the sour sop (*Annona muricata*), the custard apple (*Annona reticulata*), the cherimoyer or cherimoya (*Annona cherimolia*), pond apple (*Annona glabra*), etc.

**SWEET SULTAN.** A garden plant. See CENTAUREA.

**SWEET VERNAL GRASS.** A slender European grass (*Anthoxanthum odoratum*), about 18 inches tall and bearing a loose cylindrical spike of flowers. It is noted for its pleasing odor due to coumarin, which is most noticeable when the plant is in flower. It is extensively naturalized in the United States. It has some value as forage but cattle often refuse to eat it, apparently not liking the odor. See Plate of GRASSES.

**SWEET WILLIAM, WILD.** See PHLOX.

**SWELL** (AS., OHG. *swellan*, Ger. *schwellen*, to swell). A term applied to a local thickening of a mineral deposit. The phenomenon is not uncommon in many metalliferous veins, and is caused by local expansions of the ore-bearing fissure, due to dynamic action or solution. In coal seams a similar phenomenon is often met with, but the swell here is caused by movements of the floor and roof of the coal bed.

**SWELL.** See ORGAN.

**SWELLFISH.** One of the many names applied to plectognath fishes, especially of the family Tetraodontidae, which inflate their bodies with air until they become globelike and the spines of their skin rigid, making them unpleasant morsels for an enemy to swallow. Other names are bottlefish and boxfish. A familiar example is *Tetraodon turgidus*, of the eastern

American coast waters, also called swell toad and puffer. Cf. GLOBEFISH. See Plate of PLECTOGNATH FISHES.

**SWELL SHARK.** A small, voracious gray shark (*Catullus utor*) of the family Scyllidae, common on the Pacific coast from central California to Chile, and often taken in lobster pots. When caught it will inflate its stomach with air, until its thickness is equal to a third of its length, and will float belly upward until it supposes the danger past; hence its vernacular name. See Plate of LAMPREYS AND DOGFISH.

**SWETCHINE**, svěch-ên', ANNE SOPHIE SOYMANOV (1782-1857). A Russian-French author, born in Moscow. Her father was Soymanov, the founder of the Moscow Academy. She married in 1799 General Swetchine and established at St. Petersburg a salon of much distinction, frequented by émigrés. Thus she came into touch with Joseph de Maistre in 1815, and was by him converted to Roman Catholicism. In the next year she moved to Paris, where her equally famous salon took on a distinctly religious tone. Her writings, all of a religious or contemplative character, are edited with a *Life* by Falloux (Paris, 1860); her *Letters* by the same editor (ib., 1862; 5th ed., 1881), who added a journal of her *Conversation* (ib., 1863), and *Lettres inédites* (ib., 1866). Her letters have been translated by H. W. Preston (Boston, 1867). Consult C. A. Sainte-Beuve, *Nourcaus lundis* (vol. i, Paris, 1863-72), and Edmond Scherer, *Etudes critiques sur la littérature contemporaine*, vol. i (ib., 1863).

**SWETE**, swēt, HENRY BARCLAY (1835- ). An English clergyman, especially distinguished for his work in textual criticism. Born at Redlands, Bristol, he was educated at King's College, London, and at Caius College, Cambridge. In 1877-80 he was rector of Ashdon, Essex; in 1882-90 served as professor of pastoral theology at King's College, London; and in 1890 was made regius professor of divinity in Cambridge. In 1911 he became honorary chaplain to the King. Among his published works are two essays on the *History of the Doctrine of the Holy Spirit* (1873; 1876); an edition of *Theodore of Mopsuestia's Commentary on the Epistles of St. Paul* (1880-82); *The Old Testament in Greek* (1887-94; 3d ed., 1901-07); *The Akhmim Fragment of the Gospel of St. Peter* (1893); *The Psalms in Greek According to the Septuagint, with the Canticles* (1889; 2d ed., 1896); *The Apostles' Creed in Relation to Primitive Christianity* (1894; 3d ed., 1899); *Church Services and Service Books before the Reformation* (1896); *An Introduction to the Old Testament in Greek* (1900; 2d ed., 1902); *The Apocalypse of St. John* (1906; 2d ed., 1907); *The Appearances of Our Lord after the Passion* (1907; 2d ed., 1908); *The Holy Spirit in the New Testament* (1900; 2d ed., 1910); *The Ascended Christ* (1911); *The Holy Spirit in the Ancient Church* (1912); *The Last Discourse and Prayer of Our Lord* (1913); *The Holy Catholic Church* (1915).

**SWETTENHAM**, swēt'en-am, SIR ALEXANDER (1846- ). A British colonial administrator, brother of Sir Frank Swettenham. He was born at Derby, England, and was educated at Clare College, Cambridge. Between 1868 and 1901 he held various government offices in Ceylon, Cyprus, Singapore, and the Straits Settlements (Acting Governor, 1898 and 1900). He was Governor and Commander in Chief of Brit-

# SWIFTS AND THEIR NESTS

1. AMERICAN CHIMNEY SWIFT (*Chaetura pelagica*).  
2. TREE SWIFT AND NEST (*Macropteryx coronata*).

3. SALANGANE (*Collocalia fuciphaga*) and edible nests.  
4. PALM SWIFT (*Micropus phoenicobia*).

ish Guiana in 1901-04 and Captain General and Governor in Chief of Jamaica in 1904-07. In 1907 Jamaica was visited by a severe earthquake, which partly destroyed Kingston, the capital and seat of government. The United States government willingly sent assistance to Jamaica, but Swettenham appeared to resent American interference and aroused harsh criticism, both in the United States and Britain, for his failure cordially to avail himself of the offered relief. He retired from office the same year. In 1898 he was knighted (K.C.M.G.).

**SWETTENHAM**, SIR FRANK ATHELSTANE (1850- ). A British administrator and author, brother of Sir Alexander Swettenham. He was born at Belper, Derbyshire, and after an academic education entered the civil service of the Straits Settlements in 1870. He rose to be Resident General of the Federated Malay States (1896-1901) and Governor and Commander in Chief of the Straits Settlements (1901-04). He published: *Malay-English Vocabulary* (1880); *About Perak* (1893); *Malay Sketches* (1895); *Unaddressed Letters* (1898); *The Real Malay Pen Pictures* (1899); *British Malaya* (1906); *Also and Perhaps* (1912); *Malay-English Dictionary*, with Hugh Clifford.

**SWEYN**, swän, **SWEGEN**, svä'gen, or **SVEND**, svënd. A King of Denmark, father of Canute (q.v.). See DENMARK.

**SWIETEN**, swë'ten, **GERARD VAN** (1700-72). A Dutch physician and scholar; born at Leyden, where, after studying philosophy at Louvain, he pursued medicine under Boerhaave, whose most distinguished pupil he became. Called to Vienna in 1745 as physician in ordinary to Maria Theresa, he instilled new life into every branch of science, but especially promoted reforms in the study of medicine, which, as director of the faculty, he raised to a high standard. Reforms in the other faculties presently followed. He became custodian of the Imperial library. In science he sought his fame as an expositor of his teacher Boerhaave. In 1758 Van Swieten, having saved the life of the Empress, was created a Baron. His observations on military hygiene he deposited in *Kurze Beschreibung und Heilungsart der Krankheiten welche am öftesten in dem Feldlager beobachtet werden*. His *Commentaria in Hermanni Boerhaave Aphorismos de Cognoscendis et Curandis Morbis* (1741-42; new ed., 1787-92) hold a permanent place in medical literature.

His son **GOTTFRIED** (1733-1803) succeeded him as custodian of the Imperial library and was an intimate friend of Haydn and Mozart. For the former he adapted the text of the *Creation* from the English and wrote the text of *The Seasons*.

**SWIFT** (AS. *swift*, fleet, rapid; connected with Eng. *swoop*, *sweep*). A bird of the family *Cypselidae*, nearly related to the humming birds. The swifts are widely distributed, and some are only found in tropical countries; others are birds of passage, and spend the summer in colder parts of the world. Many are popularly called swallows, as the chimney swift (q.v.), the only swift common in the United States, almost always called chimney swallow. This is on account of a resemblance in the long, pointed wings, the small, widely gaping bill, the weak feet, and to the habit of capturing their insect prey by untiring hunting in the air. It is thus of some indirect value to man, as it feeds largely upon small beetles, flies, bugs, grasshoppers, and other injurious insects. About 75

species of swifts are known, half of which are American, although only four occur in the United States. Swifts are mostly dull-colored birds, black, brown, gray, and white, and are seldom over seven inches in length or more than twice that across the wings. They are remarkable for the development of the salivary glands, the secretion of which is used in building the nest. The latter may be nearly pure saliva, as in the edible nests of the salangane (q.v.), or (more commonly) may be composed of grass, twigs, or other vegetable matter, glued together and to the support by saliva. Nests are attached to cliffs, interiors of chimneys, hollow trees, the spathes of palm blossoms, or the leaves of palms, etc. The eggs are pure white, unspotted. Along the Pacific coast occurs also the great black swift (*Cypseloides niger*), ranging from the West Indies and Mexico north to British Columbia. It breeds on inaccessible cliffs, and is little known. Another large swift (*Cypselus*, or *Aeronautes, melanoleucus*), which has clin, throat, and breast white, occurs in the southwestern United States, north to Wyoming and Utah, and it also breeds on practically inaccessible cliffs. To the same genus as the last-named species belong the best-known European forms. In this genus, which contains about 25 species, three-fourths belonging to the Old World, the tail is usually forked, the legs and toes are feathered, and all the toes are directed forward. The common and widespread European swift is *Cypselus apus*. Another notable species is the alpine swift of the mountainous parts of South Europe. To this same genus belong the palm swifts of the West Indies, of which a Jamaican species (*Micropus phainolebia*) is noteworthy on account of its nest, which when placed in a palmetto is glued to the surface of one of the great fronds and formed of silk-cotton in the shape of a bag or watch pocket open at the side. Some of the most curious and interesting swifts dwell in the Orient. One genus (*Macropteryx*) contains the tree swifts, whose plumage is peculiarly soft, the tails deeply forked and the head crested. They are shy and breed in rocky jungles, forming a little cup-shaped nest of flakes of bark glued together with saliva and attached to the side of the branch of a tree. There is only one egg, which (as is the case with all the family) is pure white. Five species are found in the Indo-Chinese region and eastward to the Solomon Islands.

**SWIFT**. A West African gazelle. See MOHR.

**SWIFT**, BENJAMIN. See PATERSON, WILLIAM ROMAINE.

**SWIFT**, GUSTAVUS FRANKLIN (1839-1903). An American merchant, born on Cape Cod, Mass. After various business experiences he engaged in 1875 in meat-packing in Chicago, and was the first to ship meat long distances successfully. He founded and was president of the corporation of Swift & Company, one of the largest packing firms in the United States, and was a prominent member of many other similar concerns. His business enterprise did much for the trade development of Chicago.

**SWIFT**, JONATHAN (1667-1745). The greatest of English satirists, born in Dublin, Nov. 30, 1667. He was of Yorkshire origin. His father had been attracted to Ireland by the prospect of political preferment, but died before Jonathan's birth. When he was six years old, his uncle Godwin sent him to Kilkenny School, the Eton of Ireland, where Congreve and Berkeley

were his contemporaries. At 15 he was sent to Trinity College, Dublin. At Trinity the lad read much history and poetry, but was disdainful of his courses and of regulations, and received his degree only by special grace. The disturbances of the Revolution of 1688 drove him to England, and in 1689 he obtained employment as secretary to Sir William Temple (q.v.) at Moor Park in Surrey. Swift found the position trying, though he calls Temple "a man of sense and virtue." In 1694 he quarreled with his employer and returned to Ireland to seek ordination, obtaining the small living of Kilroot, near Belfast. But he wearied of rural isolation and in 1696 went back to Moor Park. Perhaps the impelling motive was the presence there of Estlin Johnson, subsequently immortalized as "Stella," the daughter of a merchant who died, and whose widow became the companion of Temple's sister, Lady Gifford, who lived with Temple at Moor Park. Swift had a hand in her education; she was now, at 15, growing into a very beautiful woman. Swift remained at Moor Park until Temple's death in 1699. His sojourn, though some incidents of it may have hurt his pride, was of inestimable value to him. Besides the daily association with a statesman and a man of culture, he had time for an enormous amount of reading and for practice in writing. His only relies, however, of this period are some Pindaric odes, a species of composition for which he was little qualified, and which Dryden characterized frankly with the judgment, "Cousin Swift, you will never be a poet."

His first prose composition betrayed his resentment. This was *The Battle of the Books* (written 1697, but not published till 1704), a burlesque of the controversy then raging over the relative merits of the ancients and the moderns, in which Swift champions the ancients, and, with the most potent and mordant satire, attacks modern pedantry in particular and modern shams in general. In 1699 he returned once more to Ireland, as secretary and chaplain to Lord Berkeley, but lost the secretaryship and did not get the expected deanery of Derry. He was, however, appointed to the rectory of Agher, with the vicarages of Laracor and Rathbeggan. Swift realized that he was a poor preacher, calling his sermons pamphlets. He soon began his career as a political pamphleteer, which was to be so epoch making, with *A Discourse on the Dissensions in Athens and Rome* (1701), really a defense of Somers and the other Whig lords threatened with impeachment. In 1704 he published the *Tale of a Tub*, the most amusing of his satirical works, the most strikingly original, and the one in which the full compass of his powers was most perfectly displayed. With matchless irony he ridiculed many forms of pretentious pedantry, mainly in literature and religion. The book led to many doubts of his orthodoxy and injured his chances of ecclesiastical preferment.

Though nominally a Whig, Swift differed from his party on important questions. He hated its war policy and its alliance with dissent. These differences, along with the failure to gain anything from the connection, made it easy for him to break from his former allies. In 1710 the Tories came into power with Harley and St. John at their head and Swift was easily won over. He turned upon the Whigs with a series of brilliant squibs, assumed the editorship of the *Examiner*, the Tory organ, Nov. 2, 1710-June

14, 1711, and produced several independent pamphlets, in all of which he ably defended the policy of the Tories. Of these particular papers the most powerful was the *Conduct of the Allies* (November, 1711), in which the position was maintained that the Whigs had prolonged the Continental War out of self-interest. Swift certainly led the way to the dismissal of Marlborough and the Peace of Utrecht (1713). For three years Swift was among the most conspicuous men in politics and society. His advent marks a new era in English politics, with the accession of public opinion, fostered by him more than by any other man, to supreme power.

The *Journal to Stella* begins in 1710. Swift had invited her in 1701 to Ireland, with her friend Mrs. Dingley. They lived in his house at Laracor and Dublin when he was absent, and in lodgings when he was present. The diary letters which he sent to Stella and Mrs. Dingley, ending with April, 1713, compose one of the most interesting documents that ever threw light on the history of a man of genius. In London he lodged close to Mrs. Vanhomrigh, whose daughter Hester (called Vanessa by him) fell in love with Swift, and hugged the chains to which Stella merely submitted. In 1714 the Tory ministry fell, Queen Anne died, and Swift's power was gone. In spite of the Queen's distrust of him, he had been appointed to the deanery of St. Patrick's in Dublin, in 1713, and thither he now retired, no doubt hoping that the move would settle his private complications for him. But, as luck would have it, Vanessa's mother died and she followed him to Celbridge, in the near neighborhood. It is possible that in 1716 Swift may have married Stella. Leslie Stephen, after a careful examination of the evidence, allows it weight, but declares it inconclusive. He undoubtedly loved her and shows a tenderness never displayed in any other case. From 1717 to 1720 he and Vanessa remained apart, but in the latter year he began to pay her regular visits. In 1723 Vanessa took the desperate step of writing to Stella. Swift rode down to Marley Abbey, where she was staying, with a terrible countenance, petrified her with a frown, and departed, flinging on the table a packet containing her letter to Stella. Vanessa died within a few weeks, leaving behind her the poem he had written for her, *Cadenus and Vanessa*, and their correspondence.

Five years afterward Stella followed Vanessa, and the wretched lover sat down the same night to record her virtues in language of unsurpassed simplicity. A lock of her hair is preserved with the inscription in Swift's handwriting, most affecting in its apparent cynicism, "Only a woman's hair." Between the death of Vanessa and that of Stella, as though withheld by an evil fate until he could no longer enjoy it, came the greatest political and literary triumph of Swift's life. He had fled to Dublin a broken man, politically extinct; a few years raised him to the summit of popularity, though power was denied him. In 1724 he took Ireland by storm with the *Drapier Letters*, a series of wonderfully effective pamphlets, directed against the patent granted to one Wood, a hanger-on of the court, for coining copper halfpence in Ireland.

The noise of this success had hardly died away when Swift acquired more lasting glory by the publication of *Gulliver's Travels*. Few books have added so much to the innocent mirth of mankind as the first two parts of *Gulliver*.

With the omission of certain passages, it is one of the most delightful children's books ever written. Yet it has been equally valued, as Swift meant it to be, for an unrivaled satire on mankind. He seems to have solaced himself with its composition in the early years of what he called his exile; and if the later books show his most savage temper, it is well to remember that they were written during the years when he was attacking political corruption and when his private happiness was being destroyed. The completed manuscript was published anonymously in the winter of 1726, meeting with instantaneous success.

His last years, however, were clouded by constantly increasing torture from disease. He governed his cathedral with great strictness and conscientiousness, and for years after Stella's death held a sort of miniature court at the deanery. But death was becoming more and more real and welcome to him. His regular farewell to a friend in these latter years was, "Good night—I hope I shall never see you again." A period of absolute mental decay closed with his death on Oct. 19, 1745. He was buried in his cathedral in the same coffin with Stella, with the epitaph written by himself, "Here lies the body of Jonathan Swift, D.D., dean of this cathedral, where burning indignation can no longer tear at his heart. Go, traveler, and imitate if you can a man who was an undaunted champion of liberty."

Swift's character, as a whole, forms a fascinating psychological study. From some passages of his life he would appear a heartless egotist; and yet he was capable of the sincerest friendship, and could never dispense with human sympathy. He is the most tragic figure in the literature of the eighteenth century. "To think of him," says Thackeray, "is like thinking of the ruins of a great empire." Nothing finer or truer could be said.

Lecky (Bohn's Library, 8 vols., London, 1897-99; new ed., 12 vols., ib., 1902-13); various selections by Stanley Lane-Poole (ib., 1884-85), by W. Lewin (Camelot Series, ib., 1886), by Henry Morley (Carisbrooke Library, ib., 1889), and by Henry Craik (ib., 1885); *Unpublished Letters* (edited by G. B. Hill, ib., 1899). Consult also W. R. Wilde, *Closing Years of Swift's Life* (Dublin, 1849); Henry Craik, *Life of Swift* (ib., 1882); Leslie Stephen, *Swift*, in "English Men of Letters Series" (New York, 1901); J. C. Collins, *Jonathan Swift: A Biographical and Critical Study* (new ed., London, 1902); S. S. Smith, *Dean Swift* (New York, 1910); *Correspondence*, edited by E. F. Ball (ib., 1914); for bibliographies, Stanley Lane-Poole, *Notes for a Bibliography of Swift*, reprinted from *The Bibliographer* (London, 1884), and W. S. Jackson, "Bibliography of the Writings of Jonathan Swift," in *Prose Works*, vol. xii (New York, 1908).

**SWIFT, JOSEPH GARDNER** (1783-1865). An American soldier, born at Nantucket, Mass. He graduated at the United States Military Academy in 1802, being the first graduate of that institution: became a captain in 1806 and a major in 1808, and in July, 1812, was promoted to be colonel and chief engineer of the United States army. In the War of 1812 he served as chief engineer of the army under General Wilkin-

son in the St. Lawrence campaign of 1813; later had charge of the construction of the fortifications of New York harbor; was brevetted a brigadier general in February, 1814; and was superintendent of the United States Military Academy by virtue of his office as chief of engineers from 1812 to 1817. He resigned from the army in November, 1818, and afterward engaged in numerous engineering enterprises.

**SWIFT, LEWIS** (1820-1913). An American astronomer, born at Clarkson, N. Y. He was educated at Clarkson Academy and about 1854 took up the study of astronomy. He was noted for his numerous discoveries of comets and nebulae previously uncatalogued. He became director of the Warner Observatory, Rochester, N. Y., in 1882. His 16-inch telescope at that institution was presented to him as a gift by the citizens of Rochester and was subsequently removed by him to the Lowe Observatory on Echo Mountain, California, where he continued his researches until failing eyesight compelled his retirement in 1901. In 1881 he was awarded the Lalande prize of the Paris Academy, and the Jackson Gwilt medal and gift of the Royal Astronomical Society in 1897. He also received several comet medals from the Astronomical Society of the Pacific.

**SWIFT, LINDSAY** (1856- ). An American librarian, bibliographer, and literary historian, born in Boston. A graduate of Harvard (1877), he became editor on the staff of the Boston Public Library. He made valuable contributions to the study of American literature and history, his publications comprising chiefly: *Massachusetts Election Sermons* (1897); *The Great Debate between Hayne and Webster* (1898); *Brook Farm* (1900); *Literary Landmarks of Boston* (1903); *Benjamin Franklin* (1910); *William Lloyd Garrison* (1911).

**SWIMMING** (from *swim*, AS., OHG. *swiman*, Ger. *schwimmen*, to swim; connected with Eng. *swamp*). The act by which an animal progresses in the water. Man is the only animal who does not swim naturally, yet keeping the head above the water is an act which most human beings may easily learn.

The swimming of quadrupeds amounts simply to walking in the water, whereas man has adopted many kinds of stroke besides the dog-paddle method by which most land animals propel themselves. These methods involve swimming on the breast, with a broad sweep of the arms and a froglike motion of the legs; swimming on the side and swimming on the back. He has also learned to float and to tread water. In the latter case the body is held in a perpendicular position and the hands and feet beat downward. The old side stroke is the favorite style for long-distance racing. It consists of three alternate motions, an under-arm and an over-arm stroke, and a scissors leg stroke, coming between the two arm strokes. The Trudgeon stroke is a form of swimming introduced into England in 1873 by J. Trudgeon who said he had learned it in South America. This is virtually the same operation as the thrust form, described in 1825 by Elias, the writer on swimming. It is one of the fastest of all strokes for short distances. It consists of alternate overhead strokes, with a frog kick simultaneous with one of the arm strokes, the body swimming on the breast. There are several modifications of this stroke, notably that introduced by Alexander Meffert, the famous American amateur

mile-champion, in which the head and forearm are kept submerged as the body is pushed forward, the body being turned from the waist and the face brought above the water as the body checks between strokes.

International swimming races between the various parts of the United Kingdom are held annually, the universities of Oxford and Cambridge include swimming on the list of inter-university sports, and intercollegiate competitions take place within the universities themselves. An amalgamation of clubs in 1869 first brought swimming under organized control, and this association developed, under several successive names, into the Amateur Swimming Association in 1886. In addition to the Amateur Swimming Association, great practical good has come to the art by the establishment of classes of already good swimmers to be further instructed in the methods of rescuing drowning persons and resuscitating those apparently exhausted.

In the United States the first championship races were held in 1877 by the New York Athletic Club, and were annual thereafter up to 1888, excepting the years 1879-82. In 1888 the management was ceded to the Amateur Athletic Union. In 1896 an indoor meet was added. Swimming records are dependent to some extent upon local conditions, though as a rule the time for standard distances shows a steady improvement. The record in 1915 (made by an Australian) was 23.16 $\frac{1}{2}$ %. The 100-yard record in 1915 was 54 $\frac{3}{4}$ % seconds, made by an American. See WATER POLO.

Consult: E. T. Brewster, *Swimming* (Boston, 1910); G. H. Corsan, *At Home in the Water* (New York, 1910); Frank Sachs, *The Complete Swimmer* (London, 1912); F. E. Dalton, *Swimming Scientifically Taught* (New York, 1912); H. R. Austin, *How to Swim* (London, 1914).

**SWINBURNE**, ALGERNON CHARLES (1837-1909). An English poet, son of Admiral Charles Henry Swinburne and Lady Henrietta Jane, daughter of the third Earl of Ashburnham. He was born in London, April 5, 1837, and was educated at Eton and at Balliol College, Oxford. There he contributed prose and verse to *Undergraduate Papers*, edited by John Nichol. After three years he left Oxford (1860) without a degree and traveled on the Continent, visiting Landor at Florence (1864). Returning to England, he became closely associated with his brother romantics, Dante Gabriel Rossetti and William Morris. Having written *The Queen Mother* and *Rosamond* (1860), two dramas recalling the fire of the Elizabethan age, he published *Atalanta in Calydon* (1865), a beautiful lyric drama cast in the mold of ancient tragedy. The next year he awakened violent criticism with *Poems and Ballads*. To his assailants Swinburne replied with unmeasured scorn in *Notes on Poems and Reviews* (1866). Besides the few pieces that reasonably disturbed the moralists, the volume contained melodious lyrics, covering a wide range of motives, Hebrew, Greek, and mediæval. Swinburne now composed a series of eloquent odes, which won universal attention and again exposed him to censure. Beginning with "A Song of Italy" (1867), they reach a point where "the heights flash" in *Songs before Sunrise* (1871), celebrating the conflict between darkness and dawn, tyranny and freedom in revolutionary Europe. In the meantime had appeared several lyrics on other themes, of which

the finest was "Ave atque Vale" (written in 1867), in memory of Baudelaire. In 1865 Swinburne published *Chastelard*, a romantic tragedy on the first period in the career of Mary Queen of Scots. He continued her history in *Boithwell* (1874) and afterward completed it in *Mary Stuart* (1881). The imposing trilogy is a chronicle history cast in dramatic form with no view to the stage. The poems thus far enumerated fairly represent Swinburne, his originality, his command over hitherto unsuspected sources of melody, his passion and vehemence.

With occasional fall in power, Swinburne produced *Erechtheus* (1876), a second and more restrained classical drama; a second series of *Poems and Ballads* (1878); the grand odes to Victor Hugo; various beautiful sonnets; translations from Villon; *Songs of Two Nations* (1875); *Songs of the Springtides* (1880); *Studies in Song* (1880); *Tristram of Lyonesse and Other Poems* (1882), passionate verse haunted by the rhythm of the sea; *A Century of Roundels* (1883); *A Midsummer Holiday and Other Poems* (1884); *Marino Faliero*, a tragedy (1885); *Lochrine*, a tragedy (1887); a third series of *Poems and Ballads* (1889); *The Sisters*, a tragedy (1892); *Astrophel and Other Poems* (1894); *The Tale of Balen* (1896); *Rosamund, Queen of the Lombards*, a tragedy (1899).

The earlier attitude of defiant revolt against the conventional social order, against kings and priests, prevented his appointment as laureate on the death of Tennyson in 1892, though he was acknowledged as the greatest surviving English poet. In his later years the note of rebellion was less violently sounded, and other feelings, the love of the sea and of little children, held place in his poems. As an artist in verse, by unsurpassed command of the resources of metrical technique, he takes a unique position. He invented many new rhythmic forms, and used none of the old without developing new beauties. His chief defect was the natural outcome of his exceptional facility of utterance and impatience of restraint, so that sense is often subordinate to sound. In criticism he took up the Elizabethan dramatists, though he made excursions elsewhere, not sparing contemporary singers. These essays have been partially collected in *Essays and Studies* (1875), *A Study of Shakespeare* (1880), and *Miscellanies* (1886). Into his prose Swinburne carried something of the passion of his verse. His prose, too, has caught the alliteration, resonance, and undulating rhythm of his verse. He died of pneumonia, April 10, 1909, at the house on Putney Hill, London, where he and Theodore Watts-Dunton (q.v.) had lived for many years.

Woodberry, *Swinburne*, in "Contemporary Men of Letters Series" (New York, 1905); P. E. More, in *Shelburne Essays* (3d series, ib., 1907); J. W. Mackail, *Swinburne* (Oxford, 1909); Edward Thomas, *Swinburne* (New York, 1912); E. W. Gosse, *Portraits and Sketches* (ib., 1912); John Drinkwater, *Swinburne: An Estimate* (ib., 1913); Frank Harris, in *Contemporary Portraits* (ib., 1915); also *The Fleshly School of Poetry* (London, 1871)—a pamphlet in which Robert Buchanan attacked Rossetti and Swinburne—and Swinburne's reply in *Under the Microscope* (ib., 1872).

**SWINBURNE, WILLIAM THOMAS** (1847-). An American naval officer, born at Newport, R. I. After graduating from the United States Naval Academy in 1866, he served on various stations, was promoted to commander in 1896, and commanded the *Helena* in the North Atlantic fleet during the Spanish-American War. He captured the Spanish steamer *Miguel Jovar* and participated in the engagements of Tunas and Manzanilla. In 1899 he joined the fleet under Admiral Dewey at Manila, and later assisted General Lawton in his campaign. Promoted to captain in 1901, he commanded the *Texas* in 1902-04. He was a member of the General Board in 1904-06 and in the latter year was made a rear admiral. Thereafter he was commander in chief of the Pacific squadron until 1909, in which year, after a short period at the Naval War College, he was retired.

**SWINDLING.** See FRAUD.

**SWINDON.** A municipal borough in Wiltshire, England, 77 miles west of London (Map: England, E 5). The old market town, the Svindune of Domesday, is built on an eminence commanding fine views of the surrounding country. The large locomotive and carriage works of the Great Western Railway form the town's chief source of revenue. The old town, which received a charter for a fair from Charles I, still maintains the characteristics of an agricultural centre with corn and cattle markets. Pop., 1901, 45,006; 1911, 50,751.

**SWINE** (AS. *swin*, Ger. *Schwein*, swine; connected with Lat. *suinus*, relating to swine, from *sus*, Gk. *ŷs*, *hys*, Ger. *Sau*, AS. *sugu*, *sū*, Eng. *soo*). The family Suidæ, containing those cloven-hoofed ungulate mammals whose domesticated races are called hogs or pigs. The swine are closely allied to the Hippopotomidæ on the one hand and to the Dicotylidæ on the other; the latter (peccaries, q.v.), indeed, are sometimes included in the term in popular usage. The three families form a group, Suina. Swine differ from hippopotami in their smaller size, in the terminal nostrils, and mobile, gristly snouts with which they obtain their food (largely roots and herbs) by grubbing in the ground. Each foot has four digits, two of which are functional, while the others, although elevated, are often useful in preventing the foot from too readily sinking into marshy ground. They are generally hairy, the babirusa (q.v.) being an exception. The dentition is complete and of the character exhibited by the accompanying illustration of a hog's teeth. The great canines form tusks,

DENTITION OF SWINE.

i, incisors; c, canines (tusks); pm, premolars; m, molars. The nervous system of the teeth is also shown.

which in the males (boars) become formidable weapons, and in some cases (as the babirusa) are doubly developed. The food consists largely of vegetable matter, but may include tough roots, nuts, etc., and also flesh, fish, shellfish, etc.; the stomach is simple, and there is no

cæcum (except in the peccaries). These animals are somewhat gregarious, often gathering into small bands, and some peccaries form large herds. The boars fight terrifically in competition for the favor of the females (sows), and valorously defend their young (which are usually striped); they are also courageous in resisting all foes, so that the hunting of certain species affords exciting sport. The pork is usually nutritious and palatable. The family is not large, and is mainly tropical in its distribution. The Suidæ are confined to the Old World: the Dicotylidæ to the warm latitudes of America. The type genus is *Sus*, of which the wild boar (see BOAR) of Europe and Asia is the most prominent species. India and the Malayan region have together three other species, and western Africa possibly a fifth. The African wart-hogs (q.v.) include two species of the genus *Phacochoerus*, distinguished from *Sus* principally by the huge tusks and great protuberances on the face. The Celebesian babirusa (q.v.) represents alone another genus; and the African river hogs close the list with two species. One genus and two species enumerate the peccaries. See HOG for an account of domestic races.

Fossil forms of the genus *Sus* are known in rocks of Middle Miocene to Pleistocene time in Europe, India, and Africa. The earliest representatives of the hog family appear in the Eocene of both North America and Europe, and the group reached an important stage of evolution in late Tertiary time. One notable genus, not, however, in the direct line of pig ancestry, is *Elotherium* of the Miocene, which was about the size of a rhinoceros, with large heavy head, massive shoulders, and small hind body and narrow chest, and the body supported on stilted legs that terminated in two-toed feet.

**SWINEMÜNDE**, sv'ne-mun'de. A strongly fortified port and fashionable resort on the Baltic Sea, in the Province of Pomerania, Prussia, on the island of Usedom, 37 miles north-northwest of Stettin (Map: Germany, F 2). The Swine here connects the Stettiner Haff with the sea. There is a good harbor. Formerly ships of deep draft with cargoes for Stettin used to discharge at Swinemünde. The town has valuable fisheries. Pop., 1900, 10,251; 1910, 13,914.

**SWINE PLAGUE** (Ger. *Schweinescurhe*; Fr. *pasteurellose du porc*). It is generally held that the disease of hogs known as swine plague is caused by the filtrable virus of hog cholera and that the bipolar organism (*Bacillus suiscepticus*) only plays a secondary rôle, in producing lung lesions, similar to that played by the *Bacillus cholerae suis* in producing intestinal lesions. Consult Hutya and Marek, *Special Pathology and Therapeutics of the Diseases of Domestic Animals*, vol. i (Am. ed. from 3d rev. Ger. ed. by Mohler and Eichhorn, Chicago, 1912); E. W. Hoar, *A System of Veterinary Medicine*, vol. i (ib., 1913). See HOG CHOLERA.

**SWING, DAVID** (1830-94). An American preacher, born in Cincinnati. He graduated at Miami University, Oxford, Ohio, in 1852, and began to study theology, but from 1853 to 1865 was professor of languages in his college. In 1866 he was called to the Fourth Presbyterian Church in Chicago and soon became one of the prominent clergymen of that city. In 1874 he was tried for heresy and acquitted, but, as a consequence, resigned his pastorate and withdrew from the Presbyterian ministry. Many of his congregation sympathized with him, and a

new church was organized, meeting at first in a theatre and later in the Central Music Hall, where Dr. Swing continued to preach to one of the largest congregations in Chicago till his death. His preaching, though diverging from the verbal standards of "orthodoxy," was essentially evangelical and spiritual, and marked by intellectual power. Consult J. F. Newton, *David Swing, Poet-Preacher* (Chicago, 1909; reprinted, New York, 1914).

**SWINGLE**, swin'g'l, WALTER TENNYSON (1871- ). An American agricultural botanist, born at Canaan, Pa. He graduated from the Kansas State Agricultural College in 1890, and studied abroad in 1895-96 and 1898. He had become in 1891 a special agent of the United States Department of Agriculture, for which he investigated subtropic fruits and established laboratories in Florida; became an agricultural explorer, and (after 1902) had charge of crop physiology and breeding investigations. He made several visits to the Mediterranean countries of Europe, to North Africa, and to Asia Minor, whence he introduced the date palm, pistache nut, and other useful plants, and also the fig insect to make possible the cultivation of Smyrna figs in California. In 1897, with Webber, he originated citranges, a hardy citrus fruit, by means of hybridization. Swingle invented several improvements in high-power microscopes.

**SWINGLETAIL**. See THRESHING SHARK.

**SWINOMISH**, swi-nō'mish. See SALISHAN STOCK.

**SWINTON**. A manufacturing town in Yorkshire, England, 4 miles north-northeast of Rotham (Map: England, E 3). It has railway, iron, glass, and pottery works. Pop., 1901, 12,217; 1911, 13,654.

**SWINTON AND PENDLEBURY**, pēn'd'l-bēr-i. A town in Lancashire, England, 5 miles northwest of Manchester. Cotton manufacture and brickmaking are its chief industries. Pop., 1901, 27,001; 1911, 30,759.

**SWISS CHARD**. See CHARD.

**SWISS FAMILY ROBINSON**. A story by the Swiss writer J. R. Wyss, begun by his father and published by him under the title *Der Schweizerische Robinson*. The tale is based on the idea of *Robinson Crusoe*, and has been widely popular in many languages.

**SWISS GUARD**. A famous regiment of royal bodyguards in France, composed exclusively of Swiss, first constituted by royal decree in 1616. Their fidelity was absolute and on the outbreak of the Revolution of 1789 they became very objectionable to the Parisian mob. On Aug. 10, 1792, the Swiss Guards were called on to defend the palace of the Tuileries against the revolutionists. After gallant resistance to overwhelming numbers, the Swiss were ordered to lay down their arms, and they were then massacred by the infuriated assailants, the few who escaped doing so with great difficulty. It is said that nearly 800 Swiss Guards were slain. In memory of their heroic conduct and brave death the famous Lion of Lucerne (q.v.), designed by Thorwaldsen, was carved in the face of a cliff at Lucerne, Switzerland. A feeble effort to reconstitute the Swiss Guards was made in 1815, and a body with that name was organized. But it was a poor imitation of the old corps and was easily dispersed by the revolutionists in 1830. Another Swiss Guard (Guardia Svizzera), the Papal Guard, consists

of 10 officers and 110 men. Only Swiss can enter it and the privates are not allowed to marry. Consult: Lutolf, *Die Schweizergarde in Rom* (Einsiedeln, 1859); Ternaux, *Histoire de la Terreur* (8 vols., Paris, 1863-81); Jaehn, *Die französische Armee von der grossen Revolution bis zur Gegenwart* (Leipzig, 1873); Pollio et Marcel, *Le bataillon du 10 août* (ib., 1881); H. M. Stephens, *History of the French Revolution* (2 vols., New York, 1886-91).

**SWISS POLITICAL PARTIES**. See POLITICAL PARTIES.

**SWITCHBACK**. See RAILWAYS.

**SWITCHMEN'S UNION OF NORTH AMERICA**. See RAILWAY BROTHERHOODS.

**SWITHIN**, swith'in (or, more correctly, SWITHUN), SAINT (7-862). An English ecclesiastic of the ninth century, who was chaplain to King Egbert. In 852 he was consecrated Bishop of Winchester. Swithin was buried, according to his own desire, in a place outside of his church at Winchester, where passers-by might tread upon his grave and the rain drop on it from the eaves. A century later he was canonized and his body exhumed and buried inside the church. According to the legend this translation, which was to have taken place on July 15, was delayed in consequence of violent rains, which continued without intermission for 40 days. Out of this circumstance arose the belief that if rain falls on July 15 it will continue to rain for 40 days. Consult Chambers, *Book of Days* (new ed., Philadelphia, 1911).

**SWITZERLAND** (Fr. *Suisse*, Ger. *Schweiz*). A country of Europe extending between lat. 45° 50' and 47° 45' N. and long. 6° and 10° 25' E., bounded on the west by France, on the north by Germany and the Lake of Constance, on the east by Austria-Hungary (Tirol and Vorarlberg) and Liechtenstein, and on the south by Italy and the French Department of Haute-Savoie, from which it is separated by the Lake of Geneva. Area, 15,976 square miles. It stretches over 200 miles east and west and 120 miles north and south. The boundaries are complicated and do not follow natural features, excepting that the Jura Mountains form the natural border between Switzerland and France, and the main crest of the Alps is mainly the border on the south side.

**Topography**. Switzerland is the most mountainous country of Europe, five-sevenths of the surface being divided between the Alps, which spread over the central and southern sections, and the Jura Mountains which cover the northwestern portion of the country. Between the Jura Mountains and the Alps is the Swiss high plain, the seat of the densest population surrounded by these great natural ramparts. The Jura Mountains form a generally southwest-northeast curve. Their summits do not ordinarily exceed 5000 feet, the loftiest in Switzerland being the Dôle, 5507 feet. The Juras consist of a number of parallel folds, none of them extending the whole length of the district, but covering a width of 20 to 35 miles. Between the ranges are long valleys, transverse gorges connecting one valley with another; and these features produce scenery of great beauty and variety. The slopes are covered with pine forests and an abundance of rich pastures is spread below them, mingling with the fields and vineyards which extend down to the margin of the small lakes that occupy some of the valley bottoms.

The central plain, about 1300 feet in general

elevation, is steeply walled in between the Juras and the Alps. It is a plain chiefly in contrast with the mountains around it and in other countries would be called an elevated region, thickly studded with picturesque hills. It extends in a southwest and northeast direction from the Lake of Geneva across Lake Constance to Württemberg, and has an average width of about 30 miles. Its hills are due chiefly to unequal erosion, the coarse gravel brought down from the Alps (known as "Nagelfluë," often cemented into a hard conglomerate) having been able especially to resist the destructive action of time and weather. The débris from the Alps, with which it is covered to a great depth, forms its soil, but disintegrated granites and gneisses contribute too large a proportion of sand and pebbles to make the soil very rich.

The Alps rising from this central plateau attain altitudes above 15,000 feet. The Swiss Alps are the middle part of the great highland region of south Europe, which extends in the form of a bow from the Gulf of Genoa to the plain of Hungary. They comprise two broad bands differing widely in character. The southern Swiss Alps (south of the Rhine and Rhone) begin in the west in the splendid glacier-covered chain of the Pennine Alps, which have their culmination in Monte Rosa (15,217 feet), inferior in height only to Mont Blanc in France. The Mischabelhorn, the Weisshorn, the Breithorn, and the incomparable pinnacle of the Matterhorn are among the Pennines which extend eastward to the Simplon. Over 30 summits exceed 12,000 feet. East of the Simplon extend the Lepontine Alps, the water parting between the Rhine, the Rhone, and the Po, with many valleys deeply excavated by torrents and crossed by a number of important passes to Italy. Here is the group of St. Gotthard, the central knot of this mountain world. It is the point from which radiate the mighty Alpine ranges that fill the centre and south of Switzerland. The ranges of Ticino from the south, the mountain masses extending from the Simplon in the southwest, the Bernese Oberland from the west, the Titlis group from the north, the Tödi chain from the northeast, and the mighty complex of the Grisons from the southeast, all converge upon St. Gotthard. The Grisons lie east of the Ticino valley and between the Rhine and the Inn, and their snows chiefly feed tributaries of the Rhine, many summits exceeding 10,000 feet. Lastly, south of the Inn and the most eastern group of the southern Swiss Alps are the magnificent peaks of Bernina, whose culminating point is 13,304 feet above the sea. These southern Alps are formed of crystalline rocks, huge masses of gneiss, granite, and other crystalline rocks, cropping out amid schists.

The chains of the northern Swiss Alps are separated one from another by three deep valleys: (1) that of the Aar with the lakes of Brienz and Thun, which carries nearly all the drainage of north Switzerland to the Rhine; (2) the valley of the Reuss with Lake Lucerne; and (3) the Walensee and Lake Zurich. Thus separated the four great groups of the northern Alps are: first, the Bernese Alps (Oberland), the water parting between the Aar and the Upper Rhone, which include the greatest snow mountains of the Alps; first among them the crystalline summits of the Finsteraarhorn (14,026 feet), the Jungfrau (13,672), Mönch (13,465), Eiger (13,040), Wetterhorn (12,150),

Schreckhorn (13,385), and others, a compact mass of snowy and rugged peaks with the Aletsch glacier, 16 miles long, the largest of Switzerland's glaciers. More than 20 of these summits rise over 12,000 feet above sea level. Second, the Titlis Alps, to the east of the Bernese Oberland. Third, the Alps of Glarus and Schwyz, also known by the name of their highest summit in the centre, Tödi (11,887 feet). The Rigi (5906 feet), commanding one of the magnificent views of the Alps, stands in the northwest corner of this group on the shores of Lake Lucerne. Fourth, the lower Alps, between Lakes Constance and Zurich, which nowhere reach the snow line. On the whole the southern slopes of the Swiss Alps are steep, but the northern slopes more gradual. Glaciers and perpetual snow cover 800 square miles, or about one-twentieth of the area of Switzerland. These northern Alps are of limestone and are stupendously folded, the folds being driven northwestward and piled up over each other. See ALPS.

**Hydrography.** Owing to the height of the mountains, the country is well supplied with water. Nearly every valley is traversed by a larger or smaller stream, often interrupted by picturesque waterfalls. The principal system of rivers is formed by the Rhine and its tributaries flowing to the North Sea; the Rhone draining to the Mediterranean; the Ticino which discharges finally into the Adriatic; and the Inn flowing to the Danube and the Black Sea. All the rivers in Switzerland are so rapid that they are almost useless for navigation, though their impetuous character fits them for industrial purposes. The only navigable stream of importance is the Aar tributary of the Rhine, which carries a larger volume of water to that river than the Rhine itself supplies above their point of junction. The Rhone, flowing to the southwest, reaches Lake Geneva as a muddy stream and leaves it to enter France as a clear blue river. The Ticino is the largest river sent down by Switzerland to the Po. It has a larger catchment basin than any other Swiss river and is the least fed by glaciers. The Inn flows east through the deep, narrow valley called the Engadine, and falls into the Danube at Passau, where it is much larger than the Danube itself. The glaciers are a source of perennial water supply, and since they melt most rapidly in summer, the Swiss rivers are fullest at that time of year.

The Alps are the Lake Country of southwest Europe. The lakes are remarkable for size, depth, and the grandeur and beauty of the scenery which surrounds them. Among the 15 important lakes in Switzerland, 11 are in the basin of the Aar and none in the basin of the Inn. Lakes Geneva and Constance, the largest lakes, balance each other at the opposite end of the country. Lake Geneva, partly in France, is over 200 square miles in area and has a maximum depth of 1000 feet, its bottom extending almost to the level of the Mediterranean. Lake Constance is a little smaller than Lake Geneva, not so deep, lies partly in German territory, and is the filter of the Rhine. Lake Neuchâtel, the largest lake entirely in Swiss territory, lies on the table-land, and hence is not so deep as the lakes in the longitudinal mountain valleys. Lucerne, Zurich, Brienz, Thun, and Bienna are also important lakes. Lake Lugano lies partly in Italy, and only nine miles of Lake

Maggiore belong to Switzerland. The Ticino flows through the latter on its way to the Po.

**Climate.** The distribution of climate is altitudinal rather than latitudinal. On the central plain and in the lower mountain valleys a temperate climate prevails, the mean annual temperature being about 50° F. The mean temperature diminishes on an average by three degrees for every thousand feet of elevation, so that the climate in the higher valleys is very severe. Ticino, Vaud, and Geneva enjoy an almost Italian climate, with a mean temperature of 51° F. to 53.5° F., in which southern fruits ripen. The snow line has an annual variation and likewise varies with the exposure; the lower limit of perpetual snow is at an altitude ranging from 8500 to 9500 feet. The growth of grain ceases at about 4000 feet. On the higher Alps, which are wrapped in clouds much of the time, the annual precipitation is from 78 to 97 inches; on the central plain it is 33 inches. The foehn, a warm south wind, causes some destruction by rapidly melting the snow and so producing avalanches and inundations. The climate of Switzerland, on the whole, is not favorable to agriculture, but is stimulating and healthful.

**Flora and Fauna.** The vertical zones of vegetation in the Alps correspond to the horizontal zones of Europe between lat. 46° and the Arctic circle. Olives in a few of the low valleys are succeeded by vines and the plants of middle Europe; then come in succession deciduous trees and grains, conifers, the high pastures, and shrubs and mosses, above which rises the region of perpetual snow. Oaks and chestnuts are abundant only in the more southern valleys, beech trees are numerous up to 4000 feet above the sea, and pines, larches, and fir trees thrive between 4000 and 6500 feet. Agriculture is mainly confined to the regions not above 2500 feet, but the high pastures extend far above the region of tillage.

The ibex and chamois are found in the high mountains, but all wild animals are becoming very scarce, by reason of the increasing number of sportsmen.

**Geology and Mineral Resources.** The backbone of Switzerland consists of gneiss and granite with outlying strata of the Carboniferous, Triassic, Jurassic, Cretaceous, and Tertiary formations. These strata are all thrown into a succession of gigantic folds, giving rise to great geologic complexity. Four distinct geologic zones, extending across Switzerland from southwest to northeast, are recognized. The limestone Jura region of roughly parallel folds is the first zone. The second is the plain whose rocks are chiefly sandstone covered, to a great extent, by the deposits of the ice invasions. The other zones cover the Alps, the more northern being that of the limestone Alps whose strata are greatly distorted and piled up over one another. The fourth zone consists of the great crystalline masses of the southern Swiss Alps formed of gneiss, granite, and other crystalline rocks and schists. Denudation has reduced the height of the mountains and deepened and lengthened the valleys, the larger rivers having pushed their sources back to the very heart of the mountain groups. The mining industry is of little importance. The only products of importance for export are asphalt of the Val des Travers in the Swiss Jura and hydraulic lime. Salt is worked at Bex. A little iron ore is mined in the Jura ranges, but the iron indus-

tries depend upon imports of material. A small amount of anthracite is mined near Bern of Fribourg, but Germany sends nearly 1,000,000 tons of coal to Switzerland every year, and France, Austria, and England also contribute important quantities.

**Agriculture and Stock Raising.** The soil is distributed among nearly 300,000 peasant proprietors representing more than one-half of the population. Of the total area, 28.4 per cent is unproductive; of the productive area, 35.8 per cent is in meadow and pasture, 29 per cent in forest, 18.7 per cent in fruit, 16.4 in crop and garden. Switzerland derives less support from its agricultural resources than any country of the Continent, excepting Norway. Only Solothurn, Lucerne, Schaffhausen, and Fribourg, among the cantons, produce nearly enough plant food for their own consumption. Wheat is grown up to 2500 feet above sea level, but the crop averages only about 4,000,000 bushels, while over 20,000,000 bushels are imported from other countries, chiefly Russia and the United States. Rye, oats, and potatoes are the chief crops, but potatoes are imported in large quantities. Thousands of tons of vegetables are imported. The cultivation of fruit is in a flourishing condition, and nearly all the cantons manufacture wine or spirits from it, such as the cherry brandy produced at Basel. Wine is produced in five cantons, but not in sufficient quantity to meet the country's demand. Orchards are planted everywhere in sheltered places, and grapes thrive especially in the warmer soils around Lake Geneva and some other lakes and on the southern slopes of the mountains. The warmer cantons of the south also produce chestnuts, almonds, walnuts in abundance, olives, and even lemons. Switzerland is not so rich in timber as formerly, for unscientific forestry has thinned the woods to a large extent; but a large portion of the forest area is now under government supervision. Every effort is being made to restore this source of wealth to its former magnitude; in 1904 there were planted 23,584,000 trees and, in 1914, 18,236,836.

As the climate and soil are especially favorable for hay and pasturage, the animal industries are more important than tillage. In comparison with cattle (1,443,483) the other domestic animals are much inferior in number and importance. Cattle breeding is carried on in all the cantons, and in the higher regions it is the chief and sometimes the only resource of the inhabitants. Switzerland is famous for its cheese, and the chief agricultural industries are the manufacture of cheese and condensed milk. The best cheeses are made in the Emmenthal, Maderanthal, Uferntal, and in Gruyères. Many Swiss cattle are exported for breeding purposes, while, on the other hand, the great influx of tourists in summer makes it necessary to import an average of about 50,000 beef cattle a year, chiefly from Austria and Italy, to make up for the local deficiency in beef. Goats (341,296) abound in the higher Alpine districts and are reared for their skins, flesh, and milk. In 1911 the horses numbered 144,128; mules and asses, 4717; sheep, 161,414; swine, 570,226. The lakes abound in fish, and pisciculture is promoted by 212 establishments that produce enormous quantities of fry.

**Manufactures.** Switzerland is a great manufacturing country, though it lacks coal, iron,

and seaports. Its advantages are abundant water power, markets in the adjoining countries in which to buy raw materials and sell manufactured products, good connections with seaports, and the diligence, perseverance, and skill of the people. Large quantities of the manufacturing output are produced in the homes. The textile and metal industries are of greatest importance. The cotton industry, which competes even with English manufactures, is centred chiefly in the cantons of Zurich, Glarus, Saint-Gall, and Appenzell. Swiss cotton cloths noted for fineness of texture and excellence of dyes and prints are sent all over the world. The well-known machine-made lace and embroidery industry of Switzerland is centred in Saint-Gall, Appenzell, and Neuchâtel. The great centres of the silk industry are Basel, where all kinds of silk ribbons are produced, and Zurich, where dress goods are woven. Watch making and machinery lead in the metal industries. The most important centres of watch making are Geneva, Chaux-de-Fonds, and Locle. The industry was once very prosperous, but it has suffered of late years from competition of the machine-made watches of the United States. The Swiss, however, have regained a large part of their export trade by the introduction of machinery and the manufacture of the cheaper grades of watches, which they produce by hundreds of thousands every year, five-sixths of them being sold in foreign countries. The manufacture of jewelry and music boxes, wood carving, straw plaiting, leather making, and tanning are also very important industries. The well-known machine works of Zurich, Winterthur, and Geneva export a considerable part of their output.

**Commerce.** In the special trade, exclusive of specie and bullion, imports and exports in 1902 were valued at 1,128,511,000 and 874,305,000 francs respectively; in 1907, 1,687,427,000 and 1,152,938,000; in 1913, 1,919,816,000 and 1,376,399,000.

The largest imports are grain, cattle, and other foodstuffs, cotton, coal, iron, petroleum, and groceries. Nearly all the exports are manufactures, such as cheese, wine, silk and cotton goods, watches, fine steel and iron goods (instruments, etc.), machinery, jewelry, lace, embroideries, and straw plaiting. Manufacturers do not aim to produce large quantities of cheap stuffs, except that cheap watches have, to a great extent, replaced the finer grades. They aim to make a reputation for the excellence and fineness of their goods. Nine-tenths of the import trade and three-fourths of the export trade are with Europe, chiefly with Germany, France, Italy, the United Kingdom, and Austria-Hungary. The United States sells very little except grain to Switzerland, but its purchases of cotton embroideries, silk goods, cheese, and other Swiss products are important. Switzerland's trade with the United States in three years amounted to:

	1901	1908	1913
Imports from U. S.	\$255,360	\$646,840	\$826,549
Exports to U. S. . . .	15,799,400	24,698,036	23,260,180

**Transportation and Communication.** In the absence of navigable rivers, international traffic is carried by the railroads. The main arteries are the lines from Lake Constance to

Geneva and Basel, and from the north via the St. Gotthard Tunnel to Italy. There were in operation, in 1912, 4917 kilometers (3055 miles) of state railway (exclusive of tramway, etc.). The wagon roads are admirable. Navigation is important on the lakes, where 171 steamboats belonging to 22 companies were plying in 1914.

**Banking.** The 42 banks had, in 1913, paid-up capital amounting to 244,750,000 francs. The new national bank, with headquarters at Bern and Zurich, opened in 1907 and has exclusive right of issue.

**Government.** The constitution of 1848, with the important revision of 1874 and subsequent amendments of lesser importance, constitutes the present fundamental law of Switzerland. (For the methods of amending the constitution, see REFERENDUM.) The Swiss state is composed of 25 cantons, with Bern as the capital. The constitution vests the executive power in a Federal Council of seven members elected for a term of three years by the two Houses of the Federal Legislature. Any Swiss citizen who is eligible to either branch of the Federal Legislature may be chosen to the Federal Council, except that not more than one member may be chosen from the same canton. It is the custom to choose members of the Council from the membership of the Federal Legislature and to reelect them continually for a long period of time. The work of administration is divided into seven departments, and one member of the Council is put in charge of each department, but the act of any Councilor is considered to be the act of the Council as a whole. The Council is organized under a president (President of the Confederation) and a vice president chosen by the Federal Legislature from among the Councilors to serve for a term of one year.

The powers and duties of the Federal Council are many and varied. In the domain of legislation it plays an important part, although it has no veto upon the acts of the Legislature. In this domain the Council sustains a relation to the Legislature somewhat like that of the cabinet in the parliamentary system of government. It makes an elaborate report to the Legislature, and although its members cannot at the same time be members of the Legislature, they have access to its sessions, take an active part in the deliberations, introduce legislative proposals, give their opinions upon various measures, and exert a great influence upon the work of legislation. It prepares the budget and advocates its adoption by the Legislature and takes the lead in the discussion of all important measures introduced by the government. The Federal Council also has a wide power of action in judicial affairs. It has, e.g., the settlement of a large class of administrative controversies which in other continental countries is intrusted to special administrative courts. It has a large supervisory power over the cantonal administration, particularly when the cantons are engaged in administering federal law. In addition to the above-mentioned functions the Council has the other powers usually exercised by a nation's executive.

The strictly legislative powers of the government are vested in a Federal Assembly (Bundesversammlung), consisting of two Houses, viz., the National Council (Nationalrat) and the Council of Estates (Ständerat). The two Houses hold separate sessions in all legislative matters

and joint sessions for the exercise of certain electoral and judicial functions. There is full equality between the two Houses in all matters whatsoever. The Council of Estates is composed of 44 members, or two from each canton. In three cantons which are divided, each half canton chooses one member. The tenure, amount of compensation, qualifications, mode of election, and the relations which they bear to their constituents are matters which the federal constitution does not regulate, but are left to the determination of each canton, with the result that the greatest variety of provisions prevails. The terms of members vary from one to four years. The Council of Estates elects its own president and vice president under the limitation that neither office can be filled from a canton which furnished the president for the session preceding. The National Council, or popular chamber of the Legislature, consists of members chosen by direct universal suffrage for a term of three years. The federal constitution apportions the members of the National Council according to population on the basis of one representative for every 20,000 inhabitants. In those districts which choose more than one representative the members are chosen on a general ticket. The Council elects its own officers subject to the limitation that the president and vice president must be chosen from the body of the Council and are ineligible to succeed themselves for the ensuing term. The president, in addition to his vote as a member, has a casting vote in case of a tie. The members of the National Council receive a compensation from the federal treasury. The Federal Assembly holds two regular sessions annually, beginning in June and December, each lasting about one month. The discussions take place in French, German, or Italian, according to the convenience of the speakers, while all formal readings occur in both French and German. The two Chambers meet jointly to settle conflicts of jurisdiction between the federal authorities, to grant pardons, and to elect the Federal Council, the Supreme Court, the Chancellor, and the commander of the army. The ordinary legislative power of the Federal Assembly is very wide and extends to many subjects which in the United States are left to the regulation of the States.

The judicial power of the Confederation is vested in a Supreme Court or Federal Tribunal consisting of 14 judges and a number of supernumeraries elected for a term of six years by the Federal Assembly, which also designates a president and a vice president of the court for two years. The court is divided into three sections, each of which holds a session in one of the five judicial districts into which Switzerland is divided. The seat of the court is at Lausanne in the Canton of Vaud. The jurisdiction of the Federal Court in the domain of public law extends to conflicts of authority between the Confederation and the cantons, to disputes between cantons of a public-law nature, and to complaints of the violation of individual constitutional rights. In civil matters of private law its jurisdiction extends to suits between the Confederation and the cantons or between the cantons themselves, or suits against the Confederation or between the cantons and private individuals or corporations. The Federal Tribunal is also a court of appeal from the decisions of the cantonal courts where the amount in dispute exceeds 3000 francs (about \$600).

Its criminal jurisdiction extends to cases of high treason against the Confederation or violence against the federal authorities, to offenses against the law of nations, to political offenses which cause disorder and lead to armed intervention, and to certain minor offenses.

For purposes of local government the political divisions and subdivisions of Switzerland are cantons, districts, and communes. Each canton has its own constitution and local government. With a few exceptions there is a unicameral legislative body called the Great Council, whose members are elected by popular suffrage, as a rule, for a term of three or four years. It enacts laws, votes the taxes, and supervises the administration. In the four cantons of Uri, Unterwalden, Glarus, and Appenzell primary assemblies of all the voters, in many respects like the New England town meeting, take the place of a legislative body. Such assemblies are known as the *Landsgemeinden*. The chief executive authority in the cantons is a council whose membership varies in number from five to nine. The same may be said of the term of service and the mode of election. At present the members are chosen by popular vote in a majority of the cantons; in the others they are chosen by the local legislatures. In all the cantonal constitutions except that of Fribourg the referendum (q.v.) as a means of legislation has a prominent place. The initiative likewise plays an important part in local legislation. In all the cantons except Geneva constitutional amendments may be initiated by popular petition, and in all except Fribourg, Lucerne, and Valais the same right exists in the case of ordinary statutes.

The cantons are divided into districts. The chief executive and administrative authority in the district is a sort of prefect either popularly elected or chosen by the cantonal Council. A subdivision of the district is called the commune (*Gemeinde*). In some of these the popular town meeting is the chief organ of government; in the others there is a local legislative assembly popularly elected. In all, the chief executive authority is a small council consisting of a president or mayor and not less than four members.

**Finance.** The Confederation derives most of its revenue from the customs, though considerable income is derived from posts, telegraphs, and state property and investments. The proceeds of the alcohol monopoly is divided among the cantons, one-tenth of the amount being used to combat the spread and evil effects of alcoholism. The revenue and expenditure in 1911 were 98,044,100 and 98,296,046 francs respectively; in 1912, 102,338,649 and 100,933,098. The public debt on Jan. 1, 1912, amounted to 122,350,985 francs, most of it bearing  $3\frac{1}{2}$  per cent interest. The standard of value is gold. The monetary unit is the franc, par value 19.295 cents. Metric weights and measures are used.

**Army.** There is no standing army, but a truly national militia, and the defense of the Republic rests with its citizens. The constitution prescribes military liability for every citizen from his twentieth to his forty-eighth year. Exemptions are limited, including only certain federal officials; postal, telegraph, hospital, and prison employees; the police force, clergymen, and teachers. Service, though compulsory, is not accepted unless the candidate is qualified physically, mentally, and morally, as determined after examination by a duly constituted com-

mission. Those who cannot pass the examination pay a special tax ranging from 6 to 3000 francs, depending on value of income and property. About 50 per cent of those required to report are rejected. Rejection is regarded as a misfortune. Service, though compulsory, is sought, not avoided, and is regarded as an honor as well as a patriotic duty. Another important advantage is the intense interest of the Swiss in rifle shooting. Practically every town has its rifle club and rifle matches, finally culminating in the national competition.

Regular training does not begin until the age of 20, but there exist in all the cities and towns cadet corps for the training of boys between 14 and 20, membership in which is voluntary. Examinations for the regular training take place at the age of 19. If chest measurement is not up to requirement, the candidate is reexamined in subsequent years. If physically unfit for full military service, a man is assigned to the auxiliary troops if the defect is slight; otherwise he is freed from service entirely. All such rejected men, unless called to the colors, pay the military tax up to the age of 40. All successful candidates, at the age of 20, are assigned to that branch of the service for which they are best suited, as determined by their previous occupation or business. These candidates in their first year are sent to one of the recruit schools, where they are fully armed and equipped (with the exception of underwear, a flannel shirt, and two pairs of shoes, which are provided by the recruit), and are there trained in the duties of the branch of the army to which they are assigned, for these periods: 65 days for infantry, engineers, and foot artillery; 75 days for field artillery; 90 days for cavalry; 60 days for sanitary and supply troops. At the end of the school term the man takes home his entire equipment and arms and is required to keep them in serviceable condition for the yearly inspection. While on military duty a man receives 50 centimes (10 cents) a day; on war service considerably more.

The Swiss army is divided into three classes: Auszug or Elite, the Landwehr, and the Landsturm. A soldier belongs from the age of 20 to 32 in the Auszug or Elite (first line) of the army. After the first year of this period, spent as above indicated, soldiers in the Elite, other than the cavalry, are called out six times, for a service lasting from 11 to 14 days. Cavalry stays only 10 years in the Elite, but are called out eight times for periods of 11 days each. Service in the Landwehr is from the ages of 32 to 40, the soldier being called out but once, for a period of 11 days. He then passes to the Landsturm until the age of 48. This class is armed and has received training in the previous classes. The unarmed or auxiliary Landsturm comprises all other males between 20 and 50 whose services can be made available in war for noncombatant duties. Every year in which he has no active service each man with his full equipment and arms reports, at a designated place, for inspection by the military authorities.

Provision is made by the government for any families that may be left in need during the service of the head of the family. Every man in military service is insured by the government against accident and sickness.

The field army consists of 6 divisions, 3 cavalry brigades and 3 mountain brigades, organized from the Elite troops. Each division is

recruited from its own territorial district. A division consists of 3 brigades, each of 2 regiments of 2 or 3 battalions each; 1 cyclist company; 1 machine-gun detachment; 12 batteries of field artillery; 2 howitzer batteries; 2 squadrons of cavalry; and 1 battalion of engineers. A cavalry brigade consists of 2 regiments; a mountain brigade of 2 or 3 battalions, 2 mountain batteries, and a company of engineers. Total, 106 infantry battalions, 72 field batteries, 12 howitzer batteries, 9 mountain batteries, and 8 cavalry regiments (each of 3 squadrons), besides 12 squadrons of divisional cavalry. There is a paper organization for forming these 6 divisions into 3 army corps. Total combatants in the field army are estimated at 140,000. In addition there is a separate force of 21,000 for frontier duty. Adding to these the trained and organized Landwehr and Landsturm contingents, Switzerland's army on initial mobilization should amount to about 260,000. Behind this first line is an unorganized Landsturm reserve of about 260,000 men, a part of whom are armed. Arms: infantry, Swiss repeating rifle; field artillery, a Q. F. shielded Krupp 7.5 cm. gun; heavy artillery, 8.4 and 12 cm. guns.

**Population.** The population, as calculated for June 30, 1912, was 3,831,220. The census of Dec. 31, 1910, showed 3,765,123 inhabitants, while the legal population was returned at 3,753,293 (1,845,529 males, 1,907,764 females): of the legal population, 552,011 were foreigners. Legal population of 1920 was 3,880,320; 1900, 3,315,443 (of whom 383,424 foreigners); 1888, 2,917,754 (229,650); 1860, 2,510,494 (114,483). The following table shows by cantons the area and the legal population according to the censuses of 1900 and 1910. The 1910 census

showed that German was the vernacular of 2,594,298 of the inhabitants; French, 793,264; Italian, 302,578; Romansh, 40,122; other, 23,031. The larger communal populations as calculated for June 30, 1913, were: Zurich, 200,600; Basel, 137,500; Geneva, 135,000; Bern, 90,800; Saint-Gall, 80,000; Lausanne, 69,400; Lucerne, 41,500; Chaux-de-Fonds, 38,600; Winterthur, 25,800; Neuchâtel, 24,100; Bienne, 24,000; Fribourg, 21,200.

**Education and Religion.** Instruction is compulsory and is rigidly enforced in the Protestant, but not in the Roman Catholic, cantons. The pupils number over 700,000, of whom 544,152 were in the primary schools in 1911. Among the famous institutions are the universities of Zurich, Bern, Geneva, Fribourg, Basel, Lausanne, and Neuchâtel, and the Federal Polytechnic at Zurich, which attracts pupils from all parts of Europe. In religion there is complete liberty of conscience. In 1910 Protestants numbered 2,107,814; Roman Catholics, 1,593,538; Jews, 18,462; others, 33,479.

**Ethnology.** Such human remains of the prehistoric Swiss as have been found in their lake dwellings (q.v.) ally the ancient people with the short-headed Celtic or Alpine race. Racially Switzerland is now overwhelmingly Alpine or Celtic, especially in isolated portions, with local invasions of northern and southern types. Great confusion is caused by the conflict between racial characters and environmental influences. Especially in stature is this true, the Teutonic element being shorter instead of taller.

**History.** In Roman times the country was inhabited by two races—the Helvetii, supposed to have been Celts, in the northwest; and the Rætii, who were said to be of common stock with the Etruscans, in the southeast. The Helvetii, having migrated into Gaul, were conquered by Julius Cæsar in 58 B.C., who forced the remnant of them to return to their homes. (See CÆSAR, *De Bello Gallico*, i, 1-29.) Before the close of the same century the Rætians were subdued by the armies of Augustus. When the German invasions took place, the Alemanni gained possession of the country east of the Aar, while the Burgundians settled in western Switzerland. About the close of the fifth century the Alemanni were conquered by the Franks, and their territory became a part of the Frankish dominion. Another Teutonic people, the Ostrogoths, took possession of the part of the country occupied by the Rætii, which nearly corresponded to Grisons, but their rule was of short duration. The Burgundians embraced Christianity about the end of the fifth century; the Alemanni retained their old pagan creed until the seventh century, when the band of Irish monks which had entered Gaul under St. Columban (q.v.) came among them, converted the people in vigorous fashion, and founded abbeys and churches, which survive to our own time. Switzerland made great progress under the rule of the Franks. After the dissolution of the great Carolingian realm the bulk of Switzerland was included in the Duchy of Alemannia, which became part of the German Kingdom, while the southwestern portion of the country was included in the Kingdom of Transjurane Burgundy. In 1033-34 this Burgundian portion passed under the rule of the German emperors, so that from this time the whole of Switzerland belonged to the Holy Roman Empire. In the early part of the Middle Ages feudalism flourished in the Swiss highlands even more than elsewhere. In the twelfth century the dukes of Zähringen rose to great power in Switzerland. They did much to check civil wars and to promote the prosperity of the towns. In 1178 they founded Fribourg and in 1191 Bern. On the extinction of the line of Zähringen (1218) their allodial possessions passed to the counts of Kyburg, while a number of cities were released from feudal overlordship. In the latter part of

the thirteenth century the counts of Savoy extended their domination into western Switzerland. At this time the counts of Hapsburg became a great power in the land, and in 1264 the house succeeded to the bulk of the possession of the counts of Kyburg. At this time there were a large number of petty sovereignties in Switzerland. Prominent among the ecclesiastical princes were the bishops of Basel and Geneva and the abbot of Saint-Gall. The great towns were united in self-defense, and many of them obtained charters as free Imperial cities. The Hapsburg rule soon became burdensome and tyrannical, and the resistance which opened the long struggle that was to end in Swiss independence began in the three Forest Cantons—Uri, Schwyz, and Unterwalden. Uri had received a special charter of liberties from the Emperor Frederick II in 1231 and Schwyz in 1240. They had leagued themselves together in behalf of the Emperor somewhat later. Thus they were accustomed to the idea of a mutual league when after the death of the Emperor Rudolph they sought to resist the Hapsburgs. In 1291 they allied themselves into a perpetual league, which came to be known as the Eidgenossenschaft. Subsequently they entered into an alliance with Zurich and the coalition of which it was the centre. Unterwalden received a charter similar to that of its associates from the Emperor Henry VII. In 1315 hostilities opened between Frederick of Hapsburg and the Eidgenossen, and the latter won the decisive battle of Morgarten (q.v.). The Forest Cantons then renewed their pact by a fundamental agreement which was for five centuries the basis of the political life of independent Switzerland. Lucerne (1332), Zurich (1351), Glarus and Zug (1352), and Bern (1353), entered the Confederation. Fresh wars followed with Austria, whose power in Switzerland was shattered by the victories of the confederates in 1386 at Sempach and in 1388 at Näfels. In 1415 the people of the cantons became the aggressors, invading Aargau and wresting it from Austria. Half a century later they made themselves masters of Thurgau. Swiss independence clashed with the ambitions of Charles the Bold of Burgundy. In 1476 they overthrew his armies at Grandson and Morat, and it was with the aid of Swiss mercenaries that René of Lorraine overwhelmed Charles the Bold at Nancy in 1477. In 1481 the towns of Fribourg and Solothurn were admitted into the confederacy. In 1499 the Emperor Maximilian I made a final attempt to bring Switzerland once more within the bounds of the Holy Roman Empire. He sought to draw men and supplies from the inhabitants for his Turkish war, but in vain, and was defeated in desperate engagements. Basel and Schaffhausen (1501) and Appenzell (1513) were then received into the Confederation, and its true independence began. The abbacy of Saint-Gall and the cities of Saint-Gall, Mülhausen, and Bienne became associated states with a vote in the Diet. Geneva, Neuchâtel, Valais, and Grisons also became associated states, but without a vote. In the early part of the sixteenth century the Swiss soldiers, who had become the most famous infantry in Europe, played a great, if not glorious, rôle as mercenaries in the Italian wars. After fighting successfully on the side of Milan against the French they suffered a terrible defeat at the hands of Francis I at Marignano in 1515. In 1516 they concluded the so-called Perpetual

Peace with France, after which they fought on the French side. In the course of these wars a number of Italian towns and districts (in the present Canton of Ticino) were annexed to Switzerland.

The Reformation (q.v.), which was inaugurated by Zwingli in 1519, brought dissension in the Confederation. Zurich in 1523 adopted Zwingli's opinions and was followed by Bern and other cantons of the north. The Forest Cantons remained attached to the Church of Rome. War broke out in 1531 between the Catholics and Protestants, and a small body of Zurichers was defeated at Kappel. Zwingli, who was with them as their chaplain, was slain. In 1536 Bern wrested the Pays de Vaud from the dukes of Savoy and annexed it to its own territory. In the same year Calvin settled at Geneva, which had succeeded in emancipating itself completely from the jurisdiction of Savoy and of its bishop, and the reformed doctrines spread throughout western Switzerland. During the Thirty Years' War Bern, which had become, since the conquest of Vaud, the leading canton, and Zurich contrived to maintain the neutrality of Switzerland; and in the Peace of Westphalia, in 1648, the country was formally declared to be wholly independent of the German Empire.

The complex fabric of the Swiss Confederation, with the division into two hostile religious camps, the relation between governing cantons and subjected districts, the selfish assertion of local and class interests, and the absence of any firm bond of union, was not conducive to a healthy political development. The constitution of the larger cantons became more and more aristocratic. In Zurich, Schaffhausen, and Basel the governing councils were elected by the corporations; and in Bern, Fribourg, Solothurn, and Lucerne a few families had acquired permanent rule. The French Revolution had its effect in Switzerland as elsewhere. In 1798 the country was occupied by the French, who were aided by the dissensions between the democrats and aristocrats. The old cantonal system was abolished, and the Helvetic Republic was organized. In 1803, at the dictation of Napoleon and under the Act of Mediation, the cantonal system was reestablished, with 19 cantons, six new ones being constituted—Saint-Gall, Grisons, Aargau, Thurgau, Ticino, and Vaud. After this Switzerland enjoyed peace under an orderly government and began to recover prosperity. The Congress of Vienna (1814–15) recognized the independence of Switzerland, and her perpetual neutrality and the inviolability of her territory were guaranteed by the Great Powers. The new Confederation was divided into 22 cantons (three new cantons, Geneva, Valais, and Neuchâtel, being constituted), each of which was represented in a diet, which was appointed to hold its annual meetings alternately at Bern, Zurich, and Lucerne. Three of these cantons were divided into half cantons, thus making in all 25 cantonal governments. A half canton has the same power in local government as a whole canton. In federal affairs, however, it has only half the weight. The constitution of the Confederation was the so-called Pact of 1815. By the terms of this pact emphasis was put upon the cantons, not on the Confederation. The cantons retained all power not expressly granted to the Diet. They had their own postal systems and coinage. Questions of liberty of

the press, public meeting, and religion were left to the cantons. The old abuses, however, which had crept into the constitutions of the cantons were revived, and representation in most of them became based on property qualifications. Officials, the aristocracy, and the clergy joined to oppose innovations and succeeded in doing so until the revolution of 1830 in France. From that year until 1848 Switzerland passed through a long crisis. There was strife between the democratic and aristocratic elements and then between the Catholics, who in some of the cantons retained ancient special privileges, and the Protestants, who formed a majority of the Swiss people. In Aargau a struggle took place between the Liberals and the Ultramontane party, which was settled by an unsatisfactory compromise. In Valais, where universal suffrage had put power into the hands of the reactionary party, a war took place, in which this party was victorious. It then ruled with a strong hand and forbade Protestant worship within the canton. In Lucerne the Ultramontane party so persecuted its political opponents that the latter were compelled to leave the canton. In 1844 a proposal was made in the Diet to expel the Jesuits, the chief object of Protestant attack; but that body declined to act. The Radical party then determined to resort to force; they organized bodies of armed men, called free corps, which invaded the Catholic cantons, but were defeated. The Catholic cantons then formed a league, named the Sonderbund, for defense against the free corps. There was a general clamor for its suppression, but in the Diet only 10½ votes out of 22 were in favor of that measure. The ruling party in Geneva had been with the majority, and this conduct led to a revolution in that city. One vote was thus gained against the Sonderbund, Saint-Gall added another, and a majority in the Diet in 1847 declared the illegality of the Sonderbund and decreed the expulsion of the Jesuits. The federal forces under General Dufour defeated those of the Sonderbund; the leagued cantons were made liable for all the expenses of the war, the Jesuits were expelled, and the monasteries were suppressed. An attempt was made by diplomatic notes to intimidate the Swiss government, but the revolutions of 1848 prevented further interference. This same period of civil strife was also one of intellectual and material development. The results of these stormy but profitable years were seen in part in the constitution of 1848, which bound the Confederation more firmly together and gave it at last an efficient government. It transformed Switzerland into a federal union resembling in many respects the United States. This transformation was opposed not only by the conservative cantons, but also by the reactionary governments of the surrounding countries. During the revolutionary years 1848–49 fugitives from these countries came to Switzerland, and their presence increased the irritation. Serious trouble with Prussia was barely averted in 1857, in a dispute over the Canton of Neuchâtel. This territory had fallen to Prussia by inheritance in 1707, and in 1815 it became a canton of Switzerland, with Prussia reserving her sovereign rights. Through the intervention of the French Emperor Napoleon III, Prussia was persuaded to renounce all rights of sovereignty in Neuchâtel, and so trouble was averted.

Since 1848 Switzerland has made notable

progress along political and economic lines. To the outside world the most interesting development has been in the evolution of certain processes of lawmaking. (See REFERENDUM.) The Swiss have sought to perfect the representative system by making it express the popular will more exactly. The device adopted is called proportional representation, by which minorities are given weight in the Legislature in proportion to their numbers. This practice is followed in several cantons. The revision of the constitution in 1874 established greater centralization in the legal and military systems and conferred upon the federal government more extensive powers in regard to railroads, water works, forest regulations, industry, and education. In addition the optional referendum was introduced, by which federal laws must be submitted to popular vote if required by 30,000 Swiss citizens or by eight cantons. Under the lead of the Radical party, which has controlled the National Council since 1848, the Swiss have recently adopted a programme looking in the direction of state Socialism. In 1898 the federal government began the purchase of national railways, and by 1909 all of the five great railway lines became national property. In 1908 an amendment empowering the federal government to enact regulations concerning trades and handicrafts was adopted. In 1911, after several years of consideration, the National Assembly passed a bill providing for workmen's insurance against accident and sickness, which was ratified the following year by the referendum.

For the effect of the European War of 1914 in Switzerland, see WAR IN EUROPE.

**SWIV'ELLER, DICK.** A lively young man in Dickens's *Old Curiosity Shop*, flowery in language and untidy in dress.

**SWOBO'DA, HEINRICH** (1856- ). An Austrian classical scholar, born in Vienna. He studied at the universities of Vienna and Berlin. In 1891 he became professor of history, in 1899 professor of Greek antiquities and epigraphy, and in 1911 professor of ancient history in the University of Prague. Meanwhile he had studied in Athens (1881-82, 1890), Rome (1886-87), and Asia Minor (1902). His publications include: *Thukydideische Quellenstudien* (1881); *Griechische Volksbeschlüsse* (1890); *Beiträge zur griechischen Rechtsgeschichte* (1905); *Griechische Geschichte* (3d ed., 1907); a revision of K. F. Hermann, *Griechische Staats-Altertümer*, vol. iii (1913).

**SWORD** (AS. *sweard*, Dutch *swaard*, Dan. *svaerd*, a sword, allied to Skt. *śaru*, a spear or dart). In its general sense, every steel weapon of offense or defense larger than the dagger or poniard; in modern military usage the term "sword" is used to describe the infantry or straight weapon, and "sabre" for the slightly curved weapon of the cavalryman. Although the distinction is clearly marked in Germany by the employment of *Degen* for the straight sword and *Säbel* for the curved weapon, the custom with other nations is to employ a single word for both. The sword always has been a personal weapon, so much so that in the prose and poetry of all nations it is often endowed with human as well as superhuman qualities. To surrender the sword has always been a token of submission, and the breaking of it a most im-

pressive ceremony of degradation, while to kiss the sword is even to-day with Orientals the highest form of oath and homage. The first sword was undoubtedly of hard wood, and from the widely scattered area in which it has been known, its employment must have been practically spontaneous among all the peoples whose stage of civilization rendered possible its use. Wooden swords were part of the equipment of the Indians of Virginia, according to Capt. John Smith. Greek literature refers more fre-

Asia has been more prolific in the matter of variety of blades than has Europe, e.g., the *yataghan* of the Mohammedan races with its double curve is a compact and formidable weapon, as also is the *kukri* of the Gurkhas (q.v.), which resembles the *yataghan* except that it is considerably broader in the blade. The *patá*, a long straight-hilted sword, is found in the south of India, while in the north the *katár*, a broad-bladed weapon with a crossbar handle, was for a long time in favor. The Japanese

UNITED STATES ARMY CAVALRY SWORD—MODEL 1913.

quently to the spear and bow than to the sword, as also the Roman and Hebrew writings. According to the testimony of the Greek works of art, the leaf-shaped blade sword was the one used by the Greeks in historical times, although the Greeks, almost alone of the ancient peoples, held the sword in but slight estimation. The ancient sword was usually worn on the left side suspended by a belt from the shoulder, although it was sometimes slung more forward, bringing the hilt in the front, or else suspended from a girdle around the waist. With the Egyptians the sword of bronze was carried in its leather scabbard in front of the body and thrust in the sword belt in a sloping direction from right to

swords are many in number and characteristic to a degree of the Japanese people. They may be classified as two-edged swords called *tsurugi*, and one-edged swords called in general *katana*. The *tsurugi* is the primitive weapon of Japan and is now rarely met with except as an ornament in temples. It was from 28 to 40 inches long and about  $2\frac{1}{2}$  or 3 inches wide and in the middle up to  $\frac{3}{8}$  of an inch thick. It ended in a sharp point and often thickened and broadened towards the point. It was evidently designed more for cutting than for thrusting. The *katana* or one-edged sword is also a cutting rather than a thrusting weapon, of several lengths. It is a much more handy sword than the *tsurugi*. The

USE OF SABRE IN CAVALRY CHARGE.

left. The Assyrians seem to have possessed the weapon most nearly approaching the sword of to-day. It was straight and narrow and apparently designed for thrusting as much as for cutting. The pointed sword of the Roman legionaries was invariably successful when opposed to the pointless weapons of their enemies. On the other hand most Asiatic nations to this day continue to use the sword as a cutting weapon, its curved shape usually preventing any use of the point. Thus the swords, military and civil, of to-day may be said to be descended from the European straight sword and the Eastern *scimitar* or *tulwar*. Under FENCING will be found the history of the sword up to the present day.

*katana* proper is from 2 feet, 6 inches to 2 feet, 9 inches long and was the common straight sword of the Japanese military class. The *tautô* or short sword was the weapon allowed to be worn by the tradesmen and all others not allowed to wear the *katana*. The *kuwaiken* is a small sword worn by the ladies of the military class.

The modern military sword is so constructed as to combine all the advantages of cutting and thrusting. The thrust is regarded as by far the most effective attack, but as it demands considerable skill and coolness, and as the average soldier (who in modern campaigns will in the majority of instances have been hastily taken

from civil life) cannot be always counted upon to remember his training and will very naturally use the cut, it has led to the compromise above described. A good sword is required to be sufficiently elastic to permit of its being bent, or to resist a heavy blow without breaking or other injury, and also to be strong enough to deliver a thrust without bending too much. Equally important is the requirement that it be as light as possible, consistent with the strength required, and that it be well balanced.

The military blades of to-day are all closely similar in design. They are straight or nearly straight, but sufficiently heavy towards the point to enable the soldier to deliver a very

order of merit, with seven classes, founded in 1522 and renewed by Frederick I in 1748. The decoration is a white cross of eight points, the arms separated by golden crowns. The blue medallion shows a bared sword surrounded by three crowns. The reverse bears a sword with a laurel wreath and the legend *Pro Patria*.

**SWORDBILL.** See HUMMING BIRD, and Plate of HUMMING BIRDS.

**SWORD DANCE.** A dance in which the use of a sword plays the characteristic part. Such dances, held in military attire and serving as exercises of youth, were probably a feature in the life of all ancient peoples. In Greece a dance of this character was known under the name of

Pyrrhic, and in Athens such a performance was said to have been instituted by Athena. Tacitus describes the youths of Germany as dancing naked over a bare blade, and 15 centuries later a particular form of the sword dance was described by Olaus Magnus as belonging to Denmark. This special dance was widely diffused and has survived in Germany, England, and Scot-

land. In it the number of performers was commonly six, with a leader; the movements were various, consisting of a march with weapons erect, directing them towards the centre of the ring, grasping the neighbor's blade by the hilt and point, forming the swords into a shield or rose and dancing with them in that form, leaping over and under the brands, and the like.

**SWORDFISH.** One of several fishes having an elongated snout, serviceable as a weapon; specifically, the single representative of the family Xiphiidae, related to the mackerels and common in the warmer parts of the Atlantic and occasional in the Pacific Ocean. This fish has a round, very muscular body (see Plate of SPEARFISH AND SWORDFISH), with large fins and a crescentic tail of extraordinary size and power, so that it is able to move with extreme speed and force. As the young grow, the fore part of the body and the head increase steadily in girth in proportion to posterior parts, and the upper jaw grows more and more elongated until it finally forms a flattened, sharp-edged sword composed of the consolidated vomer, ethmoid, and premaxillary bones and coated with a finely granulated hide. This weapon is about half as long as the body and becomes so strong that it may be driven far through the planking of a rowboat or even a sailing vessel, as has repeatedly happened, probably by accident. The swordfish reaches its largest size off the coast of New England, where in midsummer it comes near shore in pursuit of schools of herring, mackerel, menhaden, and other gregarious fishes upon which it mainly feeds, striking right and left. The average size in the Atlantic is about 7 feet in total length and 250 pounds in weight, but there are authentic records of fish more than twice that size. The flesh is of excellent flavor, and the capture of a swordfish is reckoned fine sport. Their spawning habits are little understood, and where they spend the winter, when

METHOD OF HOLDING SABRE.

effective cut. The French government in 1899 adopted a long sword designed only for thrusting. It is 35 inches in length of blade from hilt to point and weighs 2 pounds, 6 ounces, without the scabbard, which latter is made of steel, with a wood lining. In 1913 the United States army adopted a similar straight sword as the weapon of the cavalryman. The new sword has a blade  $35\frac{1}{8}$  inches long, is two-edged, tapering gradually to a sharp point. The guard is much larger than the old sabre and is solid, covering and protecting the hand. The weight is 2 pounds, 8 ounces. The balance is excellent. The scabbard is of wood covered with leather. It is designed to be used principally as a thrusting weapon, the cavalryman leaning well forward with head low and arm extended, so that the point is in advance of the horse's nose. The thrust is more easily executed than the cut, causes less exposure to the body, is rapidly executed, and is the most dangerous and the most difficult to parry of all the sabre strokes. The German cavalry sword is  $32\frac{1}{2}$  inches long from hilt to point and weighs 2 pounds, 8½ ounces, without the scabbard. The scabbard, like that of the French and British, is of steel with wood lining. The British cavalry officer's sword measures 35 inches from hilt to point and weighs, without the scabbard, 2 pounds, while the sword of the trooper measures  $33\frac{1}{2}$  inches and is 2 pounds, 10¼ ounces in weight. The British infantry officer's sword measures  $32\frac{1}{2}$  inches from hilt to point and weighs, without scabbard, 2 pounds, 3 ounces. In the United States army the sword proper has been abolished, and a single form of sabre is now worn by all officers. These are issued in lengths of 30, 32, and 34 inches. Consult Sir R. F. Burton, *Book of the Sword* (London, 1884). See CAVALRY; FENCING; TACTICS, MILITARY, and references there given.

**SWORD, ORDER OF THE.** A Swedish military

they disappear from the American coast, is unknown.

Several other large related fishes are called swordfish, among them the sailfish and spearfish (q.v.) of the family Istiophoridae, the large handsome papagaloo (*Nematistius pectoralis*) of the Pacific coast of tropical America, and the cutlass fish (q.v.). The best general account of the swordfish and swordfishing is by G. B. Goode, *Fishery Industries*, sec. i (Washington, 1884).

**SWORDFISHING.** The catching of swordfish is pursued in summer both for profit and sport off the coast of New England, especially in the neighborhood of Nantucket, and is often the occasion of exciting incidents. Small, swift vessels are employed, provided with a short bowsprit, at the outer end of which is set a small platform and a strong iron stanchion surmounted by a circular horizontal band at the height of a man's waist. The fisherman, standing within this contrivance, with a connecting strap buckled behind him, is held safely in spite of the pitching of the vessel, while both his arms are left free. A swordfish having been sighted at the surface, where it is feeding on menhaden or similar prey, the schooner bears down upon it until the fisherman is able to throw a barbed spear or a heavy grain into its body. To this spear a line is attached fastened inboard, and if a successful strike is made, the crew gradually haul the struggling fish near enough to be knocked on the head and disabled, if necessary. As the swordfish is big and strong, and is armed with formidable weapons in its sword and its powerful tail, strength, skill, and agility are sometimes required to overcome and secure it. Consult G. B. Goode, *Fishery Industries*, sec. i (Washington, 1884), and C. F. Holder, *Marvels of Animal Life* (New York, 1885).

**SWORD OF DAMOCLES.** See DAMOCLES.

**SYBARIS** (Lat., from Gk. Σύβαρις). A celebrated Greek colony in Magna Græcia (q.v.). It was situated in northeastern Bruttium, between the river Crathis (*Crati*) and Sybaris (*Coscile*), about 3 miles from the Tarentine gulf. It was founded by Achæans and Træzenians before 700 B.C., and it soon acquired control of territory extending entirely across the peninsula. Sybaris was a great mercantile city, with strong democratic tendencies. The luxury of the inhabitants became proverbial. During the sixth century B.C. the city had attained a circumference of more than 5 miles and ranked with Miletus as one of the most powerful of Grecian cities. The party strife which disturbed so many of the Greek mercantile communities raged here also, and towards the end of the century we find the city in the hands of a tyrant, Telys, supported by the popular party. A Crotonian noble who married Telys's daughter was exiled by his townsmen, and they also gave asylum to a large body of the banished nobles of Sybaris. The refusal of a demand for their surrender led to a war between the two cities, in which the Crotonians, in spite of inferior numbers, won a great victory, which was followed by internal strife in Sybaris, leading to the easy capture of the city (c.510 B.C.). The victors razed it and turned the bed of the Crathis over the site. The few survivors withdrew to their colonies, Scidros and Laos, on the west coast. Excavations were undertaken by the Italian government in 1879 and 1887, and two extensive necropolises were found; the site of the ancient city was not ex-

actly determined. Consult *Notizie degli Scavi*, published by the Reale Accademia dei Lincei (Rome, 1879-88), and P. Orsi, *Atti del congresso di scienze storiche*, vol. v (ib., 1904).

**SYBEL**, zē'bel, HEINRICH VON (1817-95). A German historian, born at Düsseldorf, Dec. 2, 1817. He studied four years at Berlin and at Bonn and in 1841 published the *Geschichte des ersten Kreuzzugs*. In 1844 he was professor at Bonn and two years later went to Marburg. It was there that he wrote his *Geschichte der Revolutionszeit von 1789 bis 1795* (1853-58), an important work. In 1856 he became professor at Munich, where he founded the *Historische Zeitschrift*, and in 1861 became professor at Bonn. He was director of Prussian archives in 1875 and had access to the most valuable material for his chief work, *Die Begründung des deutschen Reichs* (Munich, 1889-94; trans. by Perrin, New York, 1890-97). His point of view is distinctly Prussian. Sybel was from 1862 to 1864 and from 1874 to 1880 a member of the Prussian Diet and in 1867 was elected to the Constituent Reichstag of the North German Confederation. He died at Marburg, Aug. 1, 1895. His minor writings were published as *Vorträge und Aufsätze* (Berlin, 1885) and *Vorträge und Abhandlungen* (ib., 1897). Consult *Allgemeine deutsche Biographie*, vol. liv (Leipzig, 1909).

**SYBEL**, LUDWIG VON (1846- ). A German archaeologist, born at Marburg. He studied at Marburg, Munich, Bonn, and Göttingen and became professor of archaeology at the University of Marburg in 1877 and rector there in 1906. His publications include: *Ueber Schliemanns Troja* (1875); *Die Mythologie der Ilias* (1877); *Katalog der Skulpturen zu Athen* (1881); *Kritik des ägyptischen Ornaments* (1883); *Weltgeschichte der Kunst im Altertum* (2d ed., 1903); *Christliche Antike* (I. Einleitendes, *Katakomben*, 1906; II. *Skulptur, Architectur*, 1909).

**SYCAMORE.** A city and the county seat of Dekalb Co., Ill., 57 miles west by north of Chicago, on the Chicago Great Western and the Chicago and Northwestern railroads (Map: Illinois, G 2). It has some manufactures, which include brass products, farm implements, fences, gray iron castings, insulated wire, canned goods, etc. It has a Carnegie library and the Episcopal Female Seminary. Pop., 1900, 3653; 1910, 3926.

**SYCAMORE**, or **SYCOMORE** (OF., Fr. *sycomore*, from Lat. *sycomorus*, from Gk. συκόμορος, *sykomoros*, mulberry tree, from σύκον, *sykon*, fig + μόρον, *moron*, μόρον, *mōron*, black mulberry), *Ficus*. A genus of generally large, long-lived trees of the family Moraceæ, mostly natives of Africa and Asia. The Egyptian sycamore (*Ficus sycomorus*), supposed to be the sycamore of the Bible, is a large spreading tree often planted for shade in Egypt and western Asia, where it is abundant in forests. The figs are top-shaped and grow in clustered racemes on the trunk and oldest branches. They are sweet, well-flavored, and somewhat aromatic. The sycamore of western Europe is a species of *Acer* or maple (q.v.); those of North America, where it is one of the largest deciduous trees, are various species of *Platanus*, the plane (q.v.) tree.

**SYCAMORE INSECTS.** The sycamore or plane tree is comparatively free from insect attack, for although several caterpillars feed

upon the leaves of the tree, none seems specifically confined to it. The leaves sometimes turn brown and fall from the attacks of colonies of one of the lace bugs (*Corythucha fimbriata*), and the seed balls are attacked by a true bug (*Melanochilus numideus*), which punctures the leaves and passes the winter in a half-grown condition thrust down between the seeds in the ball. Only one borer seems specifically confined to this tree, but *Chalcophora campestris* is found burrowing into dead limbs and trunks and may hasten the death of an otherwise diseased tree. Consult A. S. Packard, *Insects Injurious to Forest Trees* (Washington, 1890).

**SYCO'SIS** (Neo-Lat., from Gk. *σύνκωσις*, *sykōsis*, figlike excrescence on the flesh, from *σύν*, *sykon*, fig). A chronic skin disease characterized by an eruption of pustules or papules, each one pierced by a hair, generally limited to the bearded face. It is commonly called barber's itch and is caused by the entrance into the hair follicles of a variety of staphylococcus, either albus, aureus, or citreus. Tinea sycosis or pustular eczema may be mistaken for it. Zinc, oil of cade, carbolic acid, ichthyol, sulphur, and betanaphthol are all recommended for its relief.

**SYDENHAM**, *sid'en-am*. A residential section and parliamentary subdistrict of Lewisham Borough, metropolitan London, 8 miles southeast of St. Paul's Cathedral (Map: London and Vicinity, F 8). It is of world-wide celebrity in connection with the Crystal Palace (q.v.), which was reerected here in 1854. Pop., 1901, 43,630; 1911, 49,758.

**SYDENHAM**, CHARLES EDWARD POULETT THOMSON, first BARON (1799-1841). A British-Canadian statesman. He was born at Wimbledon, Surrey, England. In 1815-17 and 1821-23 he was in St. Petersburg, connected with the branch establishment of his father's business, in 1819-21 and after 1823 was identified with the London house of the firm. His political associations were Liberal. In 1826 he was elected to the House of Commons for Dover and afterward for Manchester. In 1830 he was appointed Vice President of the Board of Trade in the cabinet of Earl Grey, and in 1834 became President. During his parliamentary career he procured tariff changes in the direction of free trade, tried to abolish the usury laws, helped to improve banking and factory legislation, and was prominent in negotiating commercial treaties with foreign countries. Continuing ill health compelled him to resign his seat in the House of Commons, and in 1839 he was appointed Governor-General of Canada. Lord Durham (q.v.) had reported in favor of the legislative union of Upper and Lower Canada under responsible government, and Thomson was sent out to assist in the task. He was eminently successful in accomplishing the union. In 1840 he was created Baron Sydenham of Kent and Toronto. On Sept. 4, 1841, he met with an accident from which he died at Kingston on the nineteenth of the same month. Consult G. P. Scrope, *Memoir of Lord Sydenham* (London, 1843), and Adam Shortt, *Life of Lord Sydenham*, in the "Makers of Canada Series" (Toronto, 1908). See CANADA, *History*.

**SYDENHAM**, THOMAS (1624-89). A great English physician, often called the English Hippocrates. He was born at Wingford Eagle, educated at Magdalen and All Souls colleges, Oxford, in Montpellier, France, and at Cambridge, where he graduated in medicine. About

1650 he established himself in practice in London, and soon became the foremost physician of his time. In the Civil War he was a captain of horse under Cromwell. Although his name is inseparably connected with our present knowledge of many diseases, he is especially to be remembered as the one who introduced cinchona in the treatment of malaria, and who first differentiated scarlatina and measles, classified chorea, and expounded gout. From the last-named disease he himself died. Sydenham was the first in England to place diagnosis and therapeutics upon sound bases, emphasizing the great importance of bedside experience. In his prescriptions he avoided the ridiculous compounds of his time, recommending vegetable decoctions; but, naturally, he was a strong believer in bloodletting. The use of tincture of opium (Sydenham's laudanum) was introduced by him. His *Processus Integri* (1592) was long the standard book for English practitioners. A collection of his works was published in English (1785); and the Sydenham Society of London, founded for the purpose of printing meritorious medical works, put forth his complete works in Latin in 1846, and in English in 1848. Consult R. G. Latham, *Memoir*, prefixed to a translation of Sydenham's *Works* from the Latin (London, 1848).

**SYDENHAM'S CHOREA**. See CHOREA.

**SYDNEY**. The capital of New South Wales and the oldest city in Australia, on the southern shores of Port Jackson (Map: New South Wales, F 3). It is situated about 8 miles from the sea, and the sound (Port Jackson) round which the city is built forms a fine harbor, where the largest vessels can safely anchor. Its bold and rocky shores alternating with fine beaches, present a succession of picturesque and beautiful landscapes. The narrow entrance is marked by two lighthouses. The port of Sydney has upwards of 23 miles of wharves. On Cockatoo Island are two large government dry docks; Mort's dry dock at Balmain is capable of accommodating the largest vessel trading to the port. The city is defended by modern forts and batteries, and is the chief Australian naval station. The suburbs include 41 municipalities.

The climate of Sydney is salubrious to a degree. The city has a mean temperature of 63°. The average rainfall is about 48 inches. The sandstone rock upon which the city is built affords a valuable material for building. The streets in the older parts of the town are narrow and irregular; in the newer portions they are modern, and the size and style of the buildings are second only to those of the principal cities of Europe. The University of Sydney stands on a commanding height. There are three suffragan colleges affiliated to the university—St. Paul's, St. John's, and St. Andrew's, representing respectively the Anglicans, Roman Catholics, and Presbyterians. St. Mary's Cathedral is a handsome building, and the Anglican cathedral of St. Andrew is also a fine structure. Noteworthy are the residence of the Governor, the museum, the National Art Gallery, the exchange, the customhouse, the town hall, the post office, the public grammar school, and the theatres. Sydney has a mechanics' institute equipped with all the educational and recreative conveniences of an institution of its kind. The Y. M. C. A. is similarly furnished.

There are fine botanical gardens, and a number of public parks, of which the Sydney Cen-

tenial Park is the chief. There are 747 acres of park lands in the city of Sydney, or 26 per cent of the city proper. In the suburbs and municipalities are large areas devoted to parks. Water is brought from the Cordeaux, Cataract, and Nepean rivers, and is carried to the Prospect Reservoir. The water works and abattoirs are municipal property. The very complete electric tramway service is owned by the State government. The manufactures comprise wagons, glass, pottery, boots and shoes, carriages, stoves, and tobacco, and there are car shops, distilleries, and breweries. At various points within a radius of from 30 to 100 miles large quantities of coal are mined for domestic consumption as well as for export. Its central position makes Sydney the permanent emporium of the British dependencies in the Southern Hemisphere. It maintains its position as the outlet for the products and commerce of extensive pastoral and mineral districts.

The first party of British settlers that reached Australia landed at Botany Bay on Jan. 18, 1778. The spot which had been selected being found unsuitable, it was abandoned a few days afterward, and the infant settlement was transferred to a point about 7 miles farther to the north, the place where Sydney now stands. The choice of the new locality was chiefly determined by the circumstance of a stream of fresh water found there, flowing into the deep inlet known as Sydney Cove, one of the numerous bays into which the basin of Port Jackson is divided. After the abolition of convict transportation the growth of Sydney was rapid. The installation here, on Jan. 1, 1901, of Lord Hopetoun as first Governor-General of the Australian Commonwealth consummated the federation of Australia. The population of Sydney with suburbs in 1861 was about 95,000; in 1881, 237,300; in 1891, 399,270; in 1901, 488,382; in 1911, 636,353. The municipality of Sydney (2880 acres) had 111,801 inhabitants in 1901 and 112,921 in 1911.

**SYDNEY.** A city and the capital of Cape Breton County, Nova Scotia, Canada, on Sydney harbor, on the Intercolonial and the Sydney and Louisbourg railways, 276 miles from Halifax (Map: Nova Scotia, K 4). It is connected by steamship with Montreal, Quebec, Halifax, and Newfoundland. It is an important manufacturing city, steel works employing 4000 men being located here, besides many other manufacturing industries. The value of the manufactured output in 1910 was placed at \$9,395,017, as compared with \$631,396 in 1900. Pop., 1901, 9009; 1911, 17,723.

**SYDNEY, ALGERNON.** See **SIDNEY, ALGERNON.**

**SYDNEY MINES.** A town in Cape Breton County, Nova Scotia, Canada, situated on Sydney harbor, and on the Intercolonial Railway (Map: Nova Scotia, K 4). It is connected with North Sydney by electric railways. Over 3500 men are employed here in collieries, blast and open-hearth furnaces. Pop., 1901, 3191; 1911, 7470.

**SYDOW, zē'dō, EMIL VON** (1812-73). A distinguished German cartographer, born at Freiberg, Saxony. He entered the Prussian army in 1829, and in 1838 began to publish his excellent schoolroom maps. Detailed to Berlin in 1843 as a member of the Military Examination Committee, he was subsequently intrusted with the geographical lectures at the Military Academy, which he resumed in 1860. Attached to the great general staff, he was made director

of the geographic-statistical department in 1867 and colonel in 1870. His cartographic work comprises: *Methodischer Handatlas für das wissenschaftliche Studium der Erdkunde*, 30 maps (4th ed., 1870); *Schulatlas in 42 Blättern* (32d ed., 1880); new ed. by Wagner, entitled *Sydow-Wagner, Methodischer Schulatlas*, 63 main and 50 accessory maps (16th ed., 1913); *Oro-hydrographischer Atlas*, 25 maps; and others. He contributed the reports "Ueber den kartographischen Standpunkt Europas" to *Petermanns Mitteilungen* (1857-72), and created the valuable book of reference *Registande der geographisch-statistischen Abteilung des Grossen Generalstabs* (Berlin, 1870-83).

**SYENE, si-ē'nē.** The ancient name of Assuan (q.v.), a town of Egypt.

**SYENITE** (Lat. *syenites*, from *Syene*). An igneous rock of granitic texture, composed essentially of alkali feldspar and mica, hornblende, or augite (mica syenite, hornblende syenite, augite syenite). It differs from granite in that it contains normally no quartz. Types of rock intermediate between the two, i.e., with a small quartz content, are known as quartz syenites. In some syenites the mineral nephelite is associated with the feldspar, constituting the class of nephelite syenites. The rock is used as a structural stone, but has not the same importance as granite, owing to its more limited occurrence. See **NEPHELITE**.

**SYKES, siks, FREDERICK HENRY** (1863- ). An American college president. He was born at Queensville, Ontario, graduated at Toronto University in 1885, and was scholar and fellow of Johns Hopkins University in 1891-95. He held various teaching positions up to 1903, and subsequently was professor of English literature and director of extension teaching at Columbia University (1903-10); director of technical education and professor of English, Teachers College, Columbia (1910-13); and after 1913, the first president of the Connecticut College for Women. His publications include, besides several books on English composition: *French Elements in Middle English* (1899); *Syllabus of Lectures on Shakespeare* (1903); *Lectures on the History of English Literature in the Nineteenth Century* (1904). He edited various English texts, and was appointed general editor of Scribner's "English Classics Series."

**SYKES, GEORGE** (1822-80). An American soldier, born at Dover, Del. He graduated at West Point in 1842, served in the Seminole and Mexican wars, and was brevetted captain for gallant conduct at Cerro Gordo. He fought in the first battle of Bull Run, as a major in the Federal army; was commissioned brigadier general of volunteers in September, 1861, took part in the Peninsular, in the second Bull Run, and in the Antietam campaigns; was commissioned major general of volunteers in November, 1862; fought at Fredericksburg and Chancellorsville; and commanded the Fifth Corps at Gettysburg. In March, 1865, he was brevetted brigadier general in the regular army for his services in the battle of Gettysburg and major general in the regular army for his services during the war. He was mustered out of the volunteer army in January, 1866, but remained in the regular army first as lieutenant colonel and then as colonel until his death in 1880. A monument has been erected in his honor at West Point.

**SYKES**, OLIVE LOGAN. Best known by her maiden name. See **LOGAN, OLIVE**.

**SYLLA**. See **SULLA**.

**SYLLABUS ERRO'RUM** (Lat., catalogue of errors). A document published by Pius IX in 1864, condemning eighty doctrines which it calls "the principal errors of our times." The text of the document and an English translation are given in Schaff, *Creeds of Christendom* (New York, 1877-78). The Syllabus gave rise in England to a famous controversy between Gladstone and Newman. Consult W. E. Gladstone, *Vaticanism* (London, 1875), and J. H. Newman, *Letters to the Duke of Norfolk* (ib., 1875). The name "syllabus" is also used for the decree of Pius X, 1907, condemning modernism in 65 propositions. See **MODERNISM**.

**SYLLOGISM** (Lat. *sylogismus*, from Gk. *συλλογισμός*, reasoning, conclusion). The name of a logical operation when expressed in a certain form in accordance with the principles of formal logic. When we reason, or get at truth by means of inference, we are said to proceed either inductively (see **INDUCTION**) or deductively. Deductive reasoning, when formally and methodically expressed, takes the form called the syllogism. "This thing will sink in water, for it is a stone," is a deductive argument, but not formally stated; this is called an enthymeme (q.v.). The complete form is, "Stones sink in water; this is a stone; therefore, this sinks in water." Such a form as this is called a syllogism.

A perfect syllogism requires (1) that there should be three, and no more than three, propositions contained in it: these are the conclusion, or the matter to be proved, and two others that are the means of proving it, called the premises; and (2) that there should be three, and no more than three, terms, viz., the subject and the predicate of the conclusion, and one, called the middle term, which must occur in both premises, being the connecting link for bringing the two other terms together in the conclusion. The predicate of the conclusion is called the major term, because it is in its extension (q.v.) the largest of the three; the subject of the conclusion is the minor term, as being the smallest in extension. The major and minor terms are called extremes. The three terms appear in the premises in this manner: the major term and the middle term appear in one premise, called the major premise; the middle term and the minor term in the minor premise. In the syllogism above stated the terms are "(a thing that will) sink in water" (major), "this thing" (minor), "stone" (middle); the premises are, "stones sink in water" (major), "this thing is a stone" (minor); the conclusion is, "this thing sinks in water." Other requisites for a complete syllogism are that (3) one premise at least must be affirmative; that (4) if one premise be negative, the conclusion must be negative; that (5) the middle term must be distributed (= taken in the whole of its extension) in at least one premise; that (6) an extreme, if undistributed in a premise, may not be distributed in the conclusion. Any syllogism which violates any one or more of these six syllogistic rules is invalid. There are two other rules which are derivative: (7) one premise at least must be universal; (8) if one premise be particular, the conclusion must be particular also. Any syllogism which violates either of these rules violates also one

or more of the first six rules given above. For the discussion of the question as to the evidence of these canons, see **LOGIC**.

Categorical syllogistic forms are divided into figures, and each figure into moods, which are the distinct syllogistic forms, the principle of division being as follows: The figure is determined by the function of the middle term, in the two premises; it may be the subject of the major premise and the predicate of the minor (first figure); the predicate in both (second figure), the subject in both (third figure), the predicate of the major and the subject of the minor (fourth figure). The fourth figure did not belong to the original scheme of Aristotle, and it is usually considered as both unnatural and unnecessary, being only an awkward inversion of the first. The syllogisms of each figure are said to differ in mood, or according to the quality and the quantity of the propositions—i.e., according as these are affirmative or negative (quality), universal or particular (quantity).

A conditional or hypothetical syllogism has a conditional judgment as a major premise, and a minor premise which either categorically asserts what appears as a mere supposition in the protasis of the major premise, or denies the apodosis in the major premise. The conclusion in the former case categorically asserts the truth of the apodosis; in the latter case denies the truth of the protasis. Examples: If A is B, C is D; but A is B; hence C is D (*modus ponens*). If A is B, C is D; but C is not D; hence A is not B (*modus tollens*). A disjunctive syllogism may be illustrated by the arguments: A is either B or C; but it is B; hence it is not C; or A is either B or C; but it is not B, hence it is C.

A conditional syllogism whose conditional major premise presents some sort of alternative is called a dilemma. We may have these cases: Either (a) alternative consequences may be asserted to follow upon a single condition (or combination of conditions), or (b) alternative conditions may be asserted to determine a single consequence (or combination of consequences); or (c) an alternative may be presented between a condition with its consequence and another condition with its separate consequence. If alternative consequences are asserted to follow upon a single condition, then it is possible to have a valid conditional syllogism either when a minor premise affirms the condition, warranting as conclusion the affirmation of the alternative consequence; or when a minor premise denies conjunctively (neither—nor) the alternative consequences, warranting as conclusion the denial of the antecedent. If alternative conditions are asserted to determine a single consequence, it is possible to have a valid syllogism when a minor premise either categorically affirms one of the conditions or disjunctively affirms both conditions, in either case justifying as conclusion the affirmation of the consequent; or when the minor premise categorically denies the consequent, justifying as conclusion the conjunctive denial of the conditions. If the major premise presents an alternative between a condition with its consequence and another condition with its separate consequence, a valid syllogism obtains when the minor premise either disjunctively affirms the two conditions, justifying the disjunctive affirmation of the two consequences, or when the minor premise conjunctively or disjunctively denies both consequences, justifying

a conjunctive or disjunctive denial respectively of the two antecedents.

Many logicians maintain that syllogistic logic is a useless formalism, for no one, it is claimed, actually reasons in the syllogistic manner. Consult: Knight Dunlap, "A Theory of the Syllogism," in *University of California, Publications: Philosophy*, vol. i (Berkeley, 1904); Franz Hillebrand, *Die neuen Theorien der kategorischen Schlüsse: eine logische Untersuchung* (Vienna, 1891); G. Rodier, "Les fonctions du syllogisme," in *L'Année philosophique*, vol. xix (Paris, 1909); also references under LOGIC. See also CONVERSION; DILEMMA; FALLACY; OBVERSION.

**SYLPHS** (Neo-Lat. *sylpha*, probably from Gk. *σὺλφῃ*, *silphē*, sort of beetle; so called as being a spirit flying in the air). In the fantastic system of the Paracelsists, the elemental spirits of the air, who, like the other elemental spirits, hold an intermediate place between immaterial and material beings. They eat, drink, speak, move about, beget children, and are subject to infirmities like men; but, on the other hand, they resemble spirits in being more nimble and swift in their motions, while their bodies are more diaphanous than those of the human race. They also surpass the latter in their knowledge, both of the present and the future, but have no soul, and when they die nothing is left.

In common usage, the term "sylph" has a feminine signification, and is applied to a graceful maiden. How this change of meaning occurred is not certain, but it is possibly owing to the popularity of Pope's *Rape of the Lock*. Consult Paracelsus' *Liber de Nymphis, Sylphis, Pygmaeis et Salamandris et cæteris Spiritibus* (Basel ed. of Paracelsus' works, 1590).

**SYLVANITE**. A telluride of gold and silver occurring with other tellurides in the Cripple Creek district of Colorado.

**SYLVESTER**. The name of two popes. **SYLVESTER I**, Pope 314-335. His reign was the first in the new period of Church freedom under Constantine. In his pontificate the Council of Nicæa was held, which he did not himself attend, but sent two legates to represent him. Numerous unhistorical legends, especially concerning his relations to Constantine, have clustered about him; concerning them, consult J. J. I. Döllinger, *Fables Respecting the Popes in the Middle Ages* (Eng. trans., New York, 1872; 2d Ger. ed., Stuttgart, 1890); and see DONATION OF CONSTANTINE. His works are in Migne, *Patrologia Latina*, viii.—**SYLVESTER II**, Pope 999-1003, Gerbert by name. He was born at Aurillac in Auvergne about 940. He became head of the cathedral school at Rheims, which grew to eminence under his direction. In 983 he was made abbot of Bobbio on the nomination of Otho II, but returned to Rheims, of which he was chosen Archbishop in 991. Four years later, the deposition of his predecessor having been declared invalid, he went to Magdeburg on Otho III's invitation, and accompanied him to Italy, where he became Archbishop of Ravenna in 998, and Pope in the following year. He was a strict reformer, and was considered the most learned man of his age. The Gobar numerals, the ancestors of our modern numerals and due to the western Arabs, owe much of their prominence, if not their introduction into Europe, to Sylvester. His writings are reprinted in Migne, *Patrologia Latina*, cxxxix; also by Oleris (Paris, 1867); his letters have been trans-

lated into French (Riom, 1847). Consult: Karl Hock, *Histoire du Pape Sylvestre II et de son siècle* (trans. from Ger. by J. M. Axinger, Paris, 1842); Schultess, *Die Sagen über Sylvestre II* (Hamburg, 1893); Lux, *Sylvesters II Einfluss auf die Politik Ottos III* (Breslau, 1898); H. K. Mann, *Lives of the Popes*, vols. iv, v (London, 1910); and the book of Döllinger referred to above.—The name was also borne by two antipopes, SYLVESTER III, who contested the papal throne with Benedict IX in 1044, and SYLVESTER IV, who was put up by the Imperial party to oppose Paschal II in 1105.

**SYLVESTER**, JAMES JOSEPH (1814-97). One of the foremost English mathematicians of the nineteenth century. He was born in London, of Jewish parents, and received his early education in a Jewish school. He then attended the Royal Institution school in Liverpool, and thence proceeded to St. John's, Cambridge (1831). As a Jew he was barred from taking a degree, and it was not until the passing of the Tests Act that he obtained his B.A. at Cambridge (1872). He studied at the Inner Temple after leaving Cambridge, and was called to the bar in 1850. Sylvester was appointed professor of natural philosophy at University College, London, in 1837, and was elected fellow of the Royal Society in 1839. In 1841 he was appointed professor of mathematics in the University of Virginia, but soon after (1845) returned to England, where he took up the work of an actuary. In 1855 he became professor of mathematics at the Royal Military Academy at Woolwich, where he remained for 15 years. In 1877 he became the first professor of mathematics at Johns Hopkins University, which position he held for seven years, returning to England to accept the Savilian professorship of geometry at Oxford. He founded the *American Journal of Mathematics* and was for some years its editor.

Sylvester's contributions were almost exclusively in the form of memoirs in scientific journals and the proceedings of various societies. They are devoted chiefly to the theories of algebraic forms (see FORMS), in which he was the recognized leader of the mathematical world. He and Cayley (q.v.) contributed more than any of their contemporaries to the theory of invariants, and he may be said to have practically created the vocabulary of the subject. He also published a work on *Laws of Verse* (1870), a subject in which he always showed an interest. Consult Sylvester's *Collected Mathematical Papers* edited by H. F. Baker (3 vols., New York, 1904-10); obituary notices in various scientific journals in 1897; and Franklin, *Address Commemorative of Sylvester* (Baltimore, 1897).

**SYLVESTER**, JOSIUA (1563-1618). An English poet, born in the north of Kent. His life was divided between poetry and trade. He is mainly known for a translation, or rather paraphrase in translation (1592), of the *Semaines* (Weeks), a sacred epic by Du Bartas (q.v.). The translation had considerable influence upon Milton. Of Sylvester's original verse, all is forgotten except the beautiful sonnet beginning "Were I as base as is the lowly plaine" (in Palgrave's *Golden Treasury*). Consult his *Works*, ed. A. B. Grosart, Chertsey Worthies Library (2 vols., London, 1878).

**SYLVESTER DAGGERWOOD**. A one-act play by George Colman the Younger, produced

in 1795, a shorter form of *New Hay at the Old Market*, brought out in the same year.

**SYLVICULTURE.** See FORESTRY.

**SYLVITE.** See POTASSIUM.

**SYLVIVUS.** The Latinized name of Jacques Dubois (1478-1555), a French anatomist, born near Amiens. He studied in Paris and afterward was a lecturer on anatomy there. His anatomical discoveries and his invention of injection for use in dissection cause him to be remembered. The Sylvian fissure, the Sylvian aqueduct, and the Sylvian artery were named in his honor. His *Opera Medica* were published at Geneva in 1630.

**SYM'BIO'SIS** (Neo-Lat., from Gk. συμβίωσις, life together, from *σύν*, *syn*, together + *βίος*, *bios*, life). That condition in which two or more dissimilar organisms live together in an intimate life relation. Various types of symbiosis depend upon the type of relation existing between the organisms, the so-called symbionts.

1. Mutualistic symbiosis, or mutualism, is that condition in which each party to the symbiosis seems to derive advantage therefrom. This relation has perhaps not been proved to exist in plants, though it seems likely that mutualism exists between the legumes and the bacteria of their root tubercles. Many believe that lichens show true mutualism, the fungus symbiont supplying nitrogenous substances or other materials absorbed from the substratum, and the alga symbiont the carbohydrates. See MYCORRHIZA.

2. Antagonistic symbiosis, or parasitism, is that condition where one symbiont gains at the expense of the other. There are many illustrations of this in nature. For example, the parasitic fungi and seed plants may be regarded as securing food from their host plants, but not giving an equivalent in return, as is the case in perfect mutualism.

3. A somewhat intermediate condition is illustrated by contingent symbiosis, or helotism (q.v.). Some writers hold that lichens illustrate this type, the idea being that there is not a mutual exchange between the alga and the fungus symbiont. The fungus is supposed to gain, but the alga is supposed neither to lose nor gain.

Symbiosis may be more or less intimate. In conjunctive symbiosis the symbionts are blended together so as to form a single body, as best illustrated by the lichens. In disjunctive symbiosis the symbiosis is more temporary, or the symbionts are less completely blended, as illustrated by ectotrophic mycorrhizas.

Relations which are, perhaps, not to be regarded as symbiosis, but which nevertheless bear a close similarity to it, are frequently found. Saprophytism differs from parasitism only in that the host plant, so to speak, is dead. Recently a new life relation has been recognized, such as is found in the Indian pipe (*Monotropa*); in which case there is a root fungus which derives its food materials saprophytically from the soil. *Monotropa*, not being a green plant, gets nearly all of its food material from the fungus. Hence the relation of the two organisms taken together is saprophytism. The mutual relation of the pair is, however, symbiosis, and the whole relation may be called symbiotic saprophytism. This term may be applied to all of the mycorrhiza plants.

Among animals forms of symbiosis are to be found. An example of social symbiosis is the

case of a polyp (*Epizoanthus*) or a sea anemone (*Adamsia*), which grows on the shell inhabited by a hermit crab. Klebs states that when the crab changes its shell it seizes the anemone and carries it off to its new home. The term *physiological symbiosis* may be applied to cases among the lowest organisms where certain algae (*Zooxanthellæ*) often live in *Radiolaria* (q.v.), while similar green and yellow plants inhabit the stomach epithelium of many actinians, corals, and worms. As Hertwig says, the *Zooxanthellæ* are nourished by the carbon dioxide which is formed by the animal tissues, and breathe out oxygen, which in turn serves as food for the animal. They also form starch and other carbohydrates, and there is nothing to prevent any surplus thus formed from becoming food for the animal. A remarkable case of symbiosis, involving a structural modification, is that of a carpenter bee (of the Oriental genus *Koptorthosoma*) and a certain mite. A special chamber, with a small orifice for entry, exists in the abdomen of the bee, in which the Acari are lodged. Here it is a little difficult to draw the line between symbiosis and the parasitism, e.g., of the itch mite which burrows under the skin between the fingers.

**Social Symbiosis.** Wheeler applies this term to the relations between ants and the various beetles, crickets, cockroaches, etc., which live at their expense. Of those beetles (*Claviger*, *Pausus*, etc.) that live in ant and termite nests certain ones seem to be tolerated or ignored by the ants. So completely agreeable to the ants is the presence of certain of the Staphylinidæ that the ants regurgitate food which they give to the beetles, and the beetles in the same manner share their supply with hungry ants. The ants feed the larval beetles with as much care as they do their own larvæ. They even clean the young beetles by licking them. See ANT; BEE; COMMENSALISM; EPIPHYTE; INSECT; LICHEN; MUTUALISM; PARASITE; ROVE BEETLE; TERMITE.

Consult: *Nature*, vols. xvii, xxv (London, 1882); Brandt, in *Archiv für Anatomie und Physiologie* (Leipzig, 1882); *Mittheilungen der zoologischen Station, Naples*, vol. iv (Naples, 1883); Oskar Hertwig, *Die Symbiosis* (Jena, 1883); Frederick Keeble, *Plant-Animals: A Study in Symbiosis*, in "Cambridge Manuals of Science and Literature" (Cambridge, 1912). For symbiosis in insects, see the papers of Forel, Wasmann, Wheeler, etc.

**SYM'BOLISM** (from *symbol*, from Lat. *symbolus*, *symbolum*, from Gk. σύμβολος, *sýmbolon*, mark, token, signal, sign). The use of symbols, not merely those of the figures of speech (see RHETORIC, FIGURES OF), but those of all language, since the word symbolizes the idea and the idea symbolizes the thing. Any word has always at least two meanings, one of which is more remote and archaic than the other, as is seen in the word "spirit," which, used in its religious sense, has not now, as it once had, the meaning "breath." Corresponding to this double or multiple meaning possessed by all except the most elemental words such as "mother," there is found to be in the human psyche a double stream of mentality, the conscious and the unconscious; and just as the ordinary person is ignorant of the vanished or obsolete meanings of all the words he uses, so he is generally uninformed concerning the stream of the unconscious (q.v.), which modern psychology, particularly the branch of it called psychoanalysis (q.v.), has begun to

investigate. (See PSYCHOTHERAPY.) Symbolism may then be defined as the deeper meaning possessed by words and things, by virtue of which they become dynamic. The more symbolic a thing is the more effect it will have upon human action. The significance or dynamic power of any symbol depends naturally upon the individual's knowledge of its history; in other words, it acquires significance in proportion as its history which has been in the unconscious is brought more and more into consciousness.

Conscious symbolism, that in which two things are represented alike in some respect, is universal from the imagery of poetry to the slang of the street, from the customs of the most developed religion to the habits of the lowest order of human life. The flag as the symbol of nationality, the cross as symbol of Christianity, the dove as symbol of the Holy Ghost, are all signs of whose implied similarities both members are easily recalled to consciousness.

The symbols of the unconscious, however, are based upon a similarity, only one member of which is available for consciousness. We know that our conduct is socially serviceable or not, very frequently without realizing why we are drawn towards unsocial acts by the archaic and antisocial nature of the unconscious, which is constantly prompting us to take satisfaction in acts which are typical only of the lower and more remote and archaic stages of the evolution of human conduct. According to this modern view of symbolism many phenomena hitherto unexplained have been cleared up. Thus much of human abnormality, as manifested in crime and in many diseases, is seen to be but the conscious member of a symbolism, the other member of which is in the unconscious and is furnishing the impulsive force whose maladjustment to the requirements of human society as at present organized is the cause of the social and individual maladies. Hysteria is thus recognized as a regression to modes of mental reaction on the stimulus of environment, a regression which is due to the influence of the unconscious, and insanity of many kinds is seen to be an archaic type of conduct and is treated accordingly and with increasing success.

Symbolism is most important in the history of art, especially of Christian art. Obviously no doctrine of religion can take form in outward act without some kind of symbolism: and accordingly every detail of the ancient Roman Catholic or Eastern rites is so planned as to suggest to the worshiper one or another aspect of abstract truth. In the plan and construction of the older churches the same idea is carried out as in their cruciform shape. Early Christian art represented Jesus under numerous symbols, among the commonest being the lamb, the fish, and the Greek letters Alpha and Omega (the beginning and the end). Similarly, the olive branch denoted peace; the palm, triumph; and the anchor, faith or hope. In later art each one of the saints depicted may be recognized by some appropriate symbol, e.g., St. Andrew by a cross in the shape of an X, or St. Dominic by the lily and the star above his forehead. Consult: C. E. Clement (Mrs. Waters), *Handbook of Legendary and Mythological Art* (15th ed., Boston, 1883); R. P. Knight, *The Symbolic Language of Ancient Art and Mythology* (new ed., New York, 1892); M. A. Pottinger, *Symbolism* (Sacramento, Cal., 1905); M. E. Tabor, *Saints in Art* (New York, 1908);

Harold Bayley, *The Lost Language of Symbolism* (2 vols., Philadelphia, 1913); H. Silberger, *Probleme der Mystik und ihrer Symbolik* (Vienna, 1914); White, "Symbolism," in *Psychoanalytic Review* (New York, 1916).

For the symbols used in mathematics, see SYMBOLS, MATHEMATICAL; FINGER SYMBOLISM; and for the use of the term "symbolism" in a restricted literary sense, see SYMBOLISTS. For words as symbols, see SEMASIOLOGY. For the use of the fish as a symbol of Christ, see ICHTHYS. SYMBOLISM, FINGER. See FINGER SYMBOLISM.

**SYM'BOLISTS.** The name of a class of writers which sprang up after 1880 notably in France and in connection with verse. The Symbolists regard symbolism as the expression of an idea by the introduction of a being or an object merely for the purposes of such expression. The characteristic means are the allegory, transposition, and allusion. The Symbolists were in effect reactionists against realism. They concern themselves with general truths in contrast with actualities. They court erudition, adore the metaphysical and mysterious, and especially exalt the magic power and charm of music. Identified with the influence of Wagner, they seek music in language and accordingly the sonorousness of words; they suggest but do not name. Dreams, visions, and mythological tales are their proper subjects, and lyricism their favorite form of poetic expression. In their aim to unify and blend the arts and the functions of the senses, the extremists among them, like Arthur Rimbaud, associated the vowels with colors, etc. The metrical reforms of the French Symbolists have resulted in making French verse more free, more subtle, intimate, and musical. The Symbolists, despite vagaries, have left a permanent and desirable mark. Their general influence has been for the exclusive, the refined, the delicate, and the mystic beauties of the supernatural. Their verse has represented idealism, religious sentiment, a return to the ancient, and an inherent preference for solemn or fatalistic themes. Verlaine, Mallarmé, and Maeterlinck are the most noteworthy of the French and Belgian Symbolists. Among Symbolist plays those of De Curel may be noted. Symbolism reaches also into the domain of contemporary painting. (See PAINTING, *Modern Painting*.) The term *Décadent* began to be derisively applied, in France, about 1882 to the group of young poets who later called themselves Symbolists. The word Symbolist represents all that proved to be durable in *décadentisme*.

The term *décadent* is sometimes used to-day, loosely, to designate by way of ridicule all modern writers, like Ibsen and D'Annunzio, whose themes at times have been atavistic, their characters degenerate, and their theories of art more or less subversive.

The Young Symbolists or *Décadent* poets, as they called themselves, in France merit distinctive notice for the rôle which they played in connection with the development of the Symbolist school or movement. Their literature may be said to have been born of the demoniacism of Baudelaire, the exaggerated realism in Zola, the haughty pessimism and gorgeous indifference of Leconte de Lisle, and the overrefining neurosis of the Goncourts, against all which influences, except that of Baudelaire, the *Décadents* nevertheless revolted wholly or in part like unnatural children. As for Baudelaire, they adoringly

adopted him as their particular sire and model. Their more immediate avatars were Verlaine and Mallarmé. Among the Décadents of Paris there developed two general groups. The less serious class associated their verse with the *chanson populaire*. They did not shrink from repulsive themes, brutal *cochonneries*, Rabelaisian wit, the authors glorying in the extravaganzas of eccentrics writing for the pavement public. Their songs were put forth in all sorts of loose, unkempt forms of verse. To whet their own morbid inspirations, they drank absinthe and used hashish and morphine. They celebrated the effects of dissipation and disease and were proud to belong among the *poètes maudits*. They were noisy poseurs, often most ingenious and clever and always surprising. Their cafés, notably the Chat Noir, were long frequented by a public greedy for the latest sensation.

It was the more serious class of Parisian Décadents who became a part of the Symbolist movement. They were the delicate and aristocratic brothers of the song writers. They reflected the same traits and motives, but in a more fine-grained, literary, and enlightened manner and in the higher forms of verse. They, too, identified themselves with urban life and exalted its factitious stimulations and the elaborate and refined corruptions of an excessive or declining civilization. They disdained the natural, the simple, the rural, the healthful. They were rare aesthetes, dwelling in Baudelaire's "artificial paradises," with anæmic, satiny complexions, victims of goaded nerves, supreme egoists, in search of the unusual, the abnormal, and the difficult. They prided themselves on being *savants mystificateurs* and were distinguished by *maladive* airs and effeminate graces. What few ideas these poets, in their effaced cult of Hartmann and Buddhism, harbored and expressed, were voluntarily involved in mystic complexity, in obscurantism. They wished to substitute sensations for ideas and art for morals. Their theories and practices in the more intimate matter of the art of poetry, however, stood out as interesting and original. It was their aim always to suggest and to mask, never to name or expose. They employed the semieffects, the neutral tones, and relied on pale motives, evaporative *nuances*, and on lingering, caressing extenuations of results. More conspicuous was their ambitious confusing of the functions of the senses, insisting on color in music and on music in color, and finding forms and perfumes in both. Their main purpose in this sphere was to interpret emotions as music and to marry it to poetry, as devoted Wagnerians. They sought to wed the flow of harmonies to liquid verse, to emphasize floating indecisions and extremely mobile sensuousnesses, earning thereby the name of *Déliquescents*. In all this they courted the neurotic, the psychical, the supernatural, and reacted against the materialistic and plastic cults of the realists and the Parnassians.

The most tangible of their innovations lay in their forms of verse—their *vers brisés*—in which they displayed attempts at blank verse or rhymed prose and strove to expand the formal and contracted limitations of French versification. They wrote "familiar alexandrines" and verse of more than 12 feet; they discarded the *césura* at the hemistich, and the alternating process of male and female rhymes. In fact, rhymes and fixed forms were generally abandoned for assonances, cadences, repetitions, and for polymorphous lines

which were meant to be the tonal and visible counterpart and representation of the themes versified.

The Décadents of Paris were specifically little more than curiosities; but in their connection with symbolism they were not without effect on literature and art. Indeed, it may almost be said that the Décadents were merely the Symbolists who failed. Among those who have been for one reason or another or at various times associated in France, in the public mind, with *décadentisme* may be mentioned (to name a few among many) Maurice Barrès, De Régnier, Gustave Kahn; the two Belgians Maeterlinck and Rodenbach; the Greek Moréas; the Americans Vielé-Griffin and Stuart Merrill. The Théâtre Libre was also to some extent identified with the Décadents. In other continental countries may perhaps be cited the Swede Ola Hansson, the Norwegian Hjalmar Christiansen, the Austrian Hermann Bahr. In England Aubrey Beardsley (q.v.), with his fantastic, unwholesome pictorial art, was considered a conspicuous Decadent. There have been no very characteristic echoes in English poetry, because blank verse, *vers libre*, etc., were not new to it. Consult: G. Pellissier, *Etudes de littérature contemporaine* (Paris, 1898); Arthur Symons, *The Symbolist Movement in Literature* (London, 1899); Gustave Kahn, *Symbolistes et décadents* (Paris, 1902); André Barre, *Le symbolisme* (ib., 1911); Rémy de Gourmont, *Le livre des masques: portraits symbolistes, gloses et documents sur les écrivains d'hier et d'aujourd'hui* (2 vols., ib., 1914). See SYMBOLISM.

**SYMBOLS, MATHEMATICAL.** The various signs and abbreviations used to facilitate mathematical expression. They are of the following kinds:

Of value.

Hindu and other numeral. See NUMERALS.

Of operation.

Addition, +, Σ.

Subtraction, −.

Multiplication, as in  $a \times b$ ,  $a \cdot b$ ,  $(a + b)$ ,  $[a \text{ or } a]$

Division, as in  $a \div b$ ,  $a : b$ ,  $a/b$ ,  $x^{-n} = \frac{1}{x^n}$ .

% (per cent, per C, per hundred, as in  $6\% = \frac{6}{100}$ ). Similarly, ‰, per mil, per thousand, per M.

Involution, as in  $x^n$ .

Evolution, as in  $x^{\frac{1}{n}}$  or  $\sqrt[n]{x}$ .

Differentiation, d, δ, D.

Integration, ∫.

Binomial coefficient  $\binom{n}{k}$ , for

$$\frac{n(n-1) \dots (n-k+1)}{k!}.$$

Of function.

$f(x)$ ,  $F(x)$ , for  $f$ —function of  $x$ ;  $F$ —function of  $x$ ;  $\phi(x, y, \dots)$ , for phi—function of  $x, y, \dots$ .

Of quality.

Positive number, +  $a$ .

Negative number, −  $a$ .

Absolute value,  $|a|$ .

Imaginary,  $ai$  for  $a\sqrt{-1}$ .

Decimal, as in 3.2 (U. S.), 3.2 (England), 3,2 (Continental).

Of relation.

Equality, =, ::.

Identity,  $\equiv$ .

Inequality, as in  $a < b$  ( $a$  less than  $b$ ),  
 $a > b$  ( $a$  greater than  $b$ ),  $a \nless b$  ( $a$  not  
less than  $b$ ),  $a \ngtr b$  ( $a$  not greater than  
 $b$ ),  $a \neq b$  ( $a$  not equal to  $b$ ).

Of continuation.

$\dots$ , as in  $a, a^2, a^3, \dots$ .

Of deduction.

$\therefore$  (since).

$\therefore$  (therefore).

Of aggregation.

$()$ ,  $[]$ ,  $\{\}$ ,  $\text{---}$ .

Of denominate numbers, as in  $\$10, 3^\circ 4' 15''$   
(degrees, minutes, seconds), £20 3s. 2d.  
(pounds, shillings, pence), cwt. (100 lbs.),  
and various abbreviations.

Of geometry.

$\angle$ ,  $\sphericalangle$  (angle, angles).

$\perp$  (perpendicular to).

$\parallel$  (parallel to).

$\sim$  or  $\cong$  (congruent to).

$\sim$  (similar to).

$\approx$  (approaches as a limit).

$\triangle$ ,  $\triangle$  (triangle, triangles).

$\odot$ ,  $\bigcirc$  (circle, circles).

$\square$ ,  $\square$  (square, squares).

$\square$ ,  $\square$  (rectangle, rectangles).

$\square$ ,  $\square$  (parallelogram, parallelograms).

$\frown$  (arc).

$\alpha$  (radians).

The question of the origin and development of mathematical symbols is a large one, and science has not yet given satisfactory answers at many points. The probable origin of the remarkable digits 1 . . . . 9 is discussed under NUMERALS. The origin of zero is unknown, there being no authentic record of its history before 400 A.D. The extension of the position system below unity is attributed to Stevin (1585), who called tenths, hundredths, thousandths, . . . . *primes*, . . . *sekondes*, *terces*, and wrote subscripts to denote the orders; thus, 4.628 was written 4<sub>(4)</sub> 6<sub>(1)</sub> 2<sub>(2)</sub> 8<sub>(3)</sub>. But Pellos (1492) used a period to set off the decimal part of a number, and a bar was used for this purpose by Rudolf (1526), Cardan (1539), Cataneo (1546), and various other writers. The first man who seems to have fully comprehended the significance of this separation of the integral and decimal parts was Rudolf, in whose *Exempelbüchle* of 1530 an example in compound interest is solved, and full use is made of the decimal fraction. Kepler (1571-1630) used the comma to set off the decimal orders, and Bürgi (1552-1632) and Pitiscus (1612) in their tables used the decimal fraction in the form 0.32, 3.2, but they also used other methods of indicating decimals. Although the early Egyptians had symbols for addition and equality, and the Greeks, Hindus, and Arabs symbols for equality and for the unknown quantity, from earliest times mathematical processes were cumbersome for lack of proper symbols of operation. The expressions for such processes were either written out in full or denoted by word abbreviations. The later Greeks, the Hindus, and Jordanus indicated addition by juxtaposition; the Italians usually denoted it by the letter  $P$  or  $p$  with a line drawn through it to distinguish it as an operation, but their symbols were not uniform. Pacioli, for example, sometimes used  $p$  and sometimes  $e$ , and Tartaglia commonly expressed the operation by  $\phi$ . The German and English algebraists introduced the sign  $+$ , but spoke of it as *signum additorum* and first employed it only to indicate excess. Subtraction

was indicated by Diophantus by the symbol  $\rho$ . The Hindus used a dot, while the Italian algebraists denoted it by  $M$  or  $m$  with a line drawn through the letter. The symbols  $\overline{m}$  and  $de$  were, however, used by Pacioli. The German and English algebraists were the first to use the present symbol and described it as *signum subtractorum*. The symbols  $+$  and  $-$  appeared first in print in an arithmetic of Widman (1489). The symbol  $\times$  for "times" is due to Oughtred (1631). To Rahn (1659) is due the sign  $\div$  for division used in the English-speaking countries; Harriot (1631) used a period to indicate multiplication, and Descartes (1637) used juxtaposition. Leibnitz in 1688 employed the sign  $\wedge$  to denote multiplication and  $\vee$  to denote division. Division among the Arabs was designated variously by

$a - b$ ,  $a/b$ ,  $\frac{a}{b}$ , but Clairaut (1760) made fami-

liar the form  $a : b$ . Descartes made popular the notation  $a^n$  for involution and Wallis defined the negative exponent. The symbol of equality,  $=$ , is due to Recorde (1557), and the symbols  $>$ ,  $<$ , for greater than and less than, originated with Harriot (1631). Viëta (1591) and Girard (1629) introduced various symbols of aggregation. The symbol  $\infty$  for infinity was first employed by Wallis in 1655. The symbols of differentiation  $dx$  and of integration  $\int$  as used in

calculus are due to Leibnitz, as is also the symbol  $\sim$  for similarity, as used in geometry. The symbolism  $\phi$ ,  $f$ ,  $F$ , as used in theory of functions, is due to Abel. Consult M. B. Cantor, *Vorlesungen über Geschichte der Mathematik* (2d ed., Leipzig, 1900); "Vorschläge zur Vereinheitlichung der mathematischen Bezeichnungen im Schulunterricht," in the *Schriften des deutschen Ausschusses für den mathematischen und naturwissenschaftlichen Unterricht* (ib., 1913), where an extended list of symbols is given.

**SYMBOLS OF THE FOUR EVANGELISTS.** See EVANGELISTS, SYMBOLS OF THE FOUR.

**SYME**, *sīm*, JAMES (1799-1870). A Scottish surgeon, born in Pife, and educated at the University of Edinburgh. He was lecturer (1823-32) and professor (1833-69) of surgery at his alma mater, after having served as demonstrator under Liston and, for a short time, as the latter's successor. He was the inventor of the mackintosh waterproof cloth. He was clinical professor from 1829 to 1833 in Minto House Hospital, which he founded at his own expense. In 1861 he was appointed surgeon in ordinary to the Queen in Scotland. He was one of the ablest teachers and operative surgeons of his time. He devised resection of the joints, Syme's amputation of the foot, and excision of the lower jaw. Syme was the father-in-law of Lord Lister (q.v.). He was the author of many valuable works, including *The Excision of Diseased Joints* (1831); *Principles of Surgery* (1832; Ger. trans.): *Diseases of the Rectum* (1838); *Pathology and Practice of Surgery* (1848); *Stricture of the Urethra and Fistula in Perineo* (1849; 2d ed., 1855). Consult R. Paterson, *Memorials of the Life of James Syme* (Edinburgh, 1874).

**SYMINGTON**, *sīm'ing-ton*, WILLIAM (1763-1831). A British inventor, born at Leadhills. In 1786 he constructed a working model of a steam road carriage, and afterward patented a steam engine in which he obtained rotary motion by chains and ratchet wheels. In 1788 he and

Patrick Miller used an engine constructed on the lines of this patent to propel a small pleasure boat on Dalswinton Loch. In the following year they experimented on a larger scale on the Forth and Clyde Canal and succeeded in attaining a speed of 7 miles an hour. As the type of engine used was imperfect, however, Symington in 1801 patented another in which a piston rod guided by rollers was connected by a rod to a crank attached to the paddle-wheel shaft. In the following year he fitted out a boat called the *Charlotte Dundas*, which proved able to tow two barges a distance of  $19\frac{1}{2}$  miles in six hours. The Duke of Bridgewater, Symington's patron, was so well pleased with the boat that he ordered eight others to be constructed. Unfortunately the Duke died soon afterward, the order was canceled, and Symington died in poverty.

**SYMMACHUS**, sĭm'mă-kŭs. Pope, 498-514. He was born in Sardinia, and was chosen to fill the vacancy left by the death of Anastasius II. A minority, however, of the Byzantine faction, set up as a rival the archpresbyter Laurentius. As a result of the schism bloody encounters took place, and the Ostrogothic King Theodoric, although an Arian, was appealed to and gave his voice for Symmachus. Theodoric, being again appealed to, caused the Bishop of Altinum to administer the affairs of the Church for a time and left the decision to a synod. In its fourth session the synod (502) finally decided in favor of Symmachus. In vindication of the action of the synod the deacon Ennodius, afterward Bishop of Ticinum (Pavia), gave clear expression to the principle that the Pope (Ennodius is among the first to limit this title to the Bishop of Rome) is above every human tribunal and is responsible only to God himself. Later councils during Symmachus' pontificate condemned all interference of laymen in the election of popes and regulated the disposition of goods belonging to the Church.

**SYMMACHUS**, GREEK VERSION OF. See *BIBLE, Versions*.

**SYMMACHUS**, QUINTUS AURELIUS (c.345-410). A Roman orator, scholar, and statesman. He was educated in Gaul, and, after holding several lesser offices, became prefect of Rome (384) and, seven years later, consul. A sincere pagan in an age when classic paganism was almost extinct, he proved a pattern of its virtues and strove to regain for it a place of honor in the state. Symmachus' extant writings consist of 10 books of letters (*Epistolarum Libri X*) and the fragments of nine orations. The best editions of Symmachus' entire works are by Seeck, in *Monumenta Germanicæ Historica: Auctores Antiquissimi*, vol. vi (Berlin, 1883), and Kroll (Leipzig, 1893). Consult: Morin, *Études sur la vie et les écrits de Symmaque, préfet de Rome* (Paris, 1847); Sir Samuel Dill, *Roman Society in the Last Century of the Western Empire* (London, 1899); T. R. Glover, *Life and Letters in the Fourth Century* (London, 1901); Martin Schanz, *Geschichte der römischen Literatur*, vol. iv, part i (2d ed., Munich, 1914); M. S. Dimsdale, *A History of Latin Literature* (New York, 1915).

**SYMMETRY** (Lat. *symmetria*, from Gk. *συμμετρία*, from *σύνμετρος*, *symmetros*, having a common measure). A term used in geometry to express a characteristic property of two congruent or quasicongruent figures which have a certain relation with respect to a point, line, or plane. Two systems of points,  $A_1, B_1, C_1, \dots$ ,

$A_2, B_2, C_2, \dots$ , are said to be symmetric with respect to an axis when all lines  $A_1 A_2, B_1 B_2, C_1 C_2, \dots$  are bisected at right angles by that

FIGURE SYMMETRIC WITH RESPECT TO AN AXIS.

axis. Two figures are said to be symmetric with respect to an axis when their systems of points are symmetric with respect to that axis. A figure is said to be symmetric with respect to an axis when the axis divides it into two symmet-

POINTS SYMMETRIC WITH RESPECT TO A CENTRE.

ric figures. Two systems of points  $A_1, B_1, C_1, \dots$ , and  $A_2, B_2, C_2, \dots$ , are said to be symmetric with respect to a centre  $O$  when all lines  $A_1 A_2, B_1 B_2, C_1 C_2, \dots$ , are bisected by  $O$ .

SYMMETRICAL TRIANGLES.

Two figures are said to be symmetric with respect to a centre when their systems of points are symmetric with respect to that centre. For example, in the figure triangles  $A_1 B_1 C_1, A_2 B_2 C_2$  are symmetric with respect to  $O$ .

Figures of three dimensions besides being symmetric with respect to an axis or a centre may be symmetric with respect to a plane. For example, the sphere is symmetric with respect to its centre, with respect to any diameter as axis, and with respect to any diametrical plane as a plane of symmetry. Symmetric polyhedral angles may be considered as quasicongruent and are such as have their dihedral angles equal, and the plane angles of their faces also equal, but arranged in reverse order.

Thus, in the following figure,  $\nabla$  and  $\nabla'$  are symmetric trihedral angles, the letters showing the reverse arrangement. Opposite polyhedral angles are such that each is formed by producing the edges and faces of the other through the vertex, and are symmetric. The theory of sym-

metric figures is closely related to that of similarity (q.v.).

In algebra, an algebraic function is said to be symmetric with respect to certain letters when these letters can be interchanged without chang-

ing the form of the expression. For example,  $x^2 + 2xy + y^2$  is symmetric as to  $x$  and  $y$ , because if  $x$  and  $y$  are interchanged it becomes  $y^2 + 2yx + x^2$ , which is the same as the original expression.

A knowledge of symmetry and homogeneity (q.v.) is of great value in factoring. For example, to factor  $f(x, y, z) = x(y^3 - z^3) + y(z^3 - x^3) + z(x^3 - y^3)$ . The expression vanishes for  $x = y$ , hence  $x - y$  is a factor by the remainder theorem (q.v.). But  $f(x, y, z)$  is symmetric with respect to  $x, y, z$ , therefore  $y - z, z - x$ , are also factors. And  $f(x, y, z)$  being homogeneous of the fourth degree, it must contain another factor of the first degree; but such a homogeneous symmetric factor can be  $x + y + z$  only. Whence the literal factors are  $x - y, y - z, z - x, x + y + z$ .

**SYMMETRY.** The general tendency in animals towards a symmetrical arrangement of parts. Thus, man is bilaterally symmetrical, i.e., the external parts or limbs are arranged in pairs on each side of his body. So with the annelid worms, the lobster, centipede, and scorpion. On the other hand, this symmetry is wanting in some of the internal organs—those which are single. Haeckel has elaborated a scheme of fundamental forms of which the following is a summary.

1. *Anaxial or symmetrical forms*, with no fixed central point or definite axis (many Protozoa and most sponges).

2. *Homaxial or spherical animals* have the fundamental shape of a sphere, the parts of the body being arranged concentrically around a fixed central point (a few spherical Protozoa, chiefly Radiolaria).

3. *Monaxial or Radial Symmetry*.—In polyps, owing to their becoming fixed in larval life, the digestive canal opens upward, the parts being arranged around the single or main axis, radiating from it. In cross section the radial symmetry is seen to be very marked. The parts are like reëntering wedges and were called by Agassiz spheromeres (coelenterates and echinoderms).

4. *Bilateral Symmetry*.—Here the parts are symmetrically arranged on each side of the main or sagittal axis (annelid worms, arthropods, vertebrates).

**Internal and External Segmentation.** This is due to the division of the body into segments, indicated externally by infoldings of the integument (annelids, tapeworms, arthropods).

The external signs of segmentation may be effaced or wanting. Thus in man the body is segmented only internally; in the lancelet the muscles are arranged segmentally and can be seen on the outside of the body. In the annelid worms (earthworm, etc.) not only is the body segmented externally, bearing setæ or parapodia on each segment, but the nerve ganglia, nephridia, or segmental organs, the vascular arches or transverse arteries, and the septa of the body, i.e., the partitions between the segments, are repeated metamerically.

**Homonomous and Heteronomous Segmentation.** The earthworm, the galley worm (*Julus*), and the centipedes afford examples where the trunk segments are for the most part alike in size and appearance, and bear similar locomotive setæ or jointed appendages. In most crustacea and insects, as well as in the higher vertebrates, heteronomy prevails. Homonomy is characteristic of the more primitive forms, heteronomy of later more specialized types. Thus, the transfer of parts headward in crabs (cephalization), due to the excessive development of certain of the head segments and the atrophy of those behind, brings about a decided irregularity in the size and shape of the segments. Heteronomy is thus accompanied by a division of physiological labor due to the specialization of the segments and their appendages. It is owing to the hypertrophy of certain segments and partial or total reduction and even in some cases loss of segments or portions of segments, with their appendages, that the varied forms of arthropods are produced.

**SYMMETRY, LAW OF, IN MINERALOGY.** See MINERALOGY.

**SYMONDS**, sîm'ûnz, JOHN ADDINGTON (1840-93). An English critic and literary historian, born at Bristol, Oct. 5, 1840. From Harrow he passed to Balliol College, Oxford, where he graduated with distinction. He began the study of law, which ill health compelled him to abandon, settled at Clifton, and began literary work in earnest. Subsequently he passed much time on the Continent, and for several years lived at Davos, in Switzerland, always in uncertain health, and often in imminent danger of a complete breakdown. *Our Life in the Swiss Highlands* (1891) tells charmingly of his mountain home. He died in Rome April 19, 1893. Symonds's reputation rests mainly on *The History of the Italian Renaissance* (7 vols., 1875-86) and the excellent translations of the *Vita di Benvenuto Cellini* (1887) and the *Sonnets of Michelangelo and Campanella* (1878). Other striking books are the *Introduction to the Study of Dante* (1872); *Shakespeare's Predecessors* (1884); *Essays Speculative and Suggestive* (1890); *In the Key of Blue* (1893); and *Walt Whitman* (1893). Symonds also contributed to the "English Men of Letters" a life of Shelley (1878) and one of Sir Philip Sidney (1886). Besides all these and much other miscellaneous work, he composed a considerable body of verse, admirable in technique but wanting in inspiration. This includes *Many Moods* (1878), *New and Old* (1880), *Animi Figura* (1882), and *Vagabunduli Libellus* (1884). Both his verse and his prose show the thorough interpenetration of his nature by the culture and the ideals of the Renaissance period with which he was so familiar. He was celebrated as a fascinating conversationalist: Stevenson, who passed some time at Davos with him, has commemorated him in the essay on "Talk and Talkers" in *Memories*

and *Portraits*, under the name of Opalstein. Consult also the biography by Horatio Brown (London, 1895), and V. Brooks, *J. A. Symonds: A Biographical Study* (New York, 1914).

**SYMONS**, sim'onz, ARTHUR (1865- ). An English author, born in Wales. He attended several private schools and traveled in France and in Italy. He wrote for the *Athenæum* and the *Saturday Review*, and was editor of the short-lived *Savoy* (1896). As a literary critic, Symons is seen to advantage in *Studies in Two Literatures* (1897), dealing with contemporary English and French writers. These essays possess a charm and finish recalling Walter Pater. He published also: *An Introduction to the Study of Browning* (1886); *The Symbolist Movement in Literature* (1899); *Cities* (1903); *Studies in Prose and Verse* (1904); *Spiritual Adventures* (1905); *Studies in Seven Arts* (1906); *William Blake* (1907); and *The Romantic Movement in English Poetry* (1909). His verse comprises: *Days and Nights* (1889); *Silhouettes* (1892); *London Nights* (1895); *Amoris Victima* (1897); *Images of Good and Evil* (1900)—all showing a marked influence of the school of French Symbolists. His *Collected Poems* (1901) contains, with some new verses, all he wished to preserve from earlier volumes. In 1913 appeared *The Knave of Hearts: 1894-1908* (poems), in 1915 *Tragedies*, in 1916 *Figures of Several Centuries*. Consult P. E. More, *Shelburne Essays, First Series* (New York, 1904).

**SYMONS**, (GEORGE) GARDNER (1861- ). An American landscape painter. He was born in Chicago, and studied at the Art Institute there, and in Paris, Munich, and London. His work, which represents chiefly snow scenes, displays decided technical ability, carefully related masses, and excellent composition, but a somewhat limited color scheme. Good examples are to be found in most public museums, including "Winter Sun" and the "Top of the Hill and Beyond" in the Chicago Art Institute; "Opalescent River" in the Metropolitan Museum, New York; "Snow Clouds," Corcoran Art Gallery, Washington; "Snowclad Fields in Morning Light," Toledo Museum; and "Sorrow," Cincinnati Museum. Later works are "Winter Evening" (1914) and "Melting Snow" (1915). In 1909 he was awarded the Carnegie prize of the National Academy of Design, of which he was elected a member in 1911. He received the prize and gold medal awarded by the National Arts Club in 1912, and in 1914 was elected to the National Institute of Arts and Letters.

**SYMONS**, GEORGE JAMES (1838-1900). An English meteorologist, born in London. From 1857 until his death he was meteorological reporter to the registrar-general, and after 1860 issued 39 annual volumes of statistics (British Rainfall) on observations, at first from 168 stations in England and Wales, but finally from 3528 stations in Great Britain and Ireland. In 1863 he started the issue of a monthly rain circular, which in 1866 developed into the *Monthly Meteorological Magazine*. Symons was president of the Meteorological Society in 1880 and in 1900.

**SYMONS DISK BREAKER AND PULVERIZER**. See GRINDING, CRUSHING, AND PULVERIZING MACHINERY.

**SYMPATHETIC INK**. See INK.

**SYMPATHY**. Literally a feeling together, a feeling for or with. The term is used to de-

note both the various modes in which a certain instinct or disposition is consciously realized, and also this instinct itself. In lower forms of animal life the instinct appears in the tendency to congregate or to live together. When the instinct is first represented in consciousness, it is touched off by a perception, and its realization is a feeling or emotion. Later in the development of the human organism, the primitive instinct is reinforced by acquired tendencies which result from continued propinquity, from the entertainment of similar ideals and aspirations, from community of language, customs, etc. Ideas, as well as perceptions, now release the disposition; and as a result our sympathies are, as we say, broadened; they extend beyond persons to animals and things. Finally, alongside of the fundamental tendency to feel with or for, there develops a particular tendency to feel in the place of another person or thing. This feeling is called "empathy." We empathize, e.g., when we become the hero in the story, when we shrink from the blow given to another, when we feel the insecurity of a column which appears too weak to bear its load. The distinction between sympathy and empathy cannot always be clearly drawn; we often sympathize and empathize at one and the same time.

Sympathy is sometimes regarded as the fundamental social instinct; and when the feeling is accompanied by the desire to do something for others, it becomes the source of altruism (q.v.). Empathy forms the basis of important theories in Aesthetics (q.v.). Consult: for Sympathy, Alexander Bain, *Emotions and Will* (New York, 1889); William James, *Principles of Psychology* (new ed., 2 vols., ib., 1905); William McDougall, *Introduction to Social Psychology* (London, 1908); T. Ribot, *Psychology of the Emotions* (2d ed., New York, 1911). For Empathy, Vernon Lee, *The Beautiful* (Cambridge, 1913); E. B. Titchener, *Beginner's Psychology* (New York, 1915).

**SYMPETALÆ**. One of the two great groups of dicotyledons (q.v.).

**SYMPHONIC POEM**. See PROGRAMME MUSIC.

**SYMPHONY** (Lat. *symphonia*, from Gk. *συμφωνία*, unison of sound, harmony, from *σύνφωνος*, *sympnōnos*, agreeing in sound, harmonious). In music, a word used in two different senses: (1) the instrumental introduction and termination of a vocal composition, sometimes called *ritornello*; (2) a composition for a full orchestra, consisting generally of four movements. The most usual though not unvarying order of movements is a brilliant allegro, frequently ushered in by a slow introduction, an adagio or andante, a scherzo with its trio, and the finale, again an allegro. For the origin of the modern symphony we must go back to the beginnings of opera early in the seventeenth century, when the name *Sinfonia* was given to the short instrumental prelude which preceded the opera. The early history of the symphony is, therefore, that of the overture (q.v.). About the middle of the eighteenth century composers began to write separate *sinfonie* exclusively for concert performance. The three parts of the older overture, which had then only a loose connection, were entirely detached and became separate movements. Stamitz (q.v.) introduced a fourth movement, the minuet (q.v.), which he inserted before the finale. He also adopted for the first movement the sonata form (q.v.). By

individualizing the separate instruments and grouping them in families Stamitz established the symphony orchestra and thus made the symphonic form practically what it is to-day. Haydn and Mozart adopted the form of Stamitz and filled it with their genius. Beethoven extended the form considerably, particularly the development section of the first movement, and replaced the minuet by the more elaborate scherzo (q.v.). On the merely formal side there has been no further development since then. The works of later masters, notably those of Schumann, Brahms, and Tchaikovsky, prove that details may be altered without affecting the fundamental principles. The Symphonic Poem (q.v.) is not a development of the Symphony. Consult: M. Brenet, *L'Histoire de la Symphonie* (Paris, 1882); S. Bagge, *Die Symphonie in ihrer historischen Entwicklung* (Leipzig, 1884); F. Weingartner, *Die Symphonie nach Beethoven* (3d ed., Berlin, 1909; Eng. trans. by Dutton, Boston, 1904); T. W. Surette, *The Development of Symphonic Music* (ib., 1915). See BEE-THOVEN; BRAHMS; STAMITZ.

**SYMPHYSIS.** See JOINT.

**SYMPLEGADES**, sim-plég'a-déz (Lat., from Gk. Συμπληγάδες (the islands), that strike together, from σύν, *syn*, together + πλῆσσειν, *plēssein*, to strike). Two mythical floating islands in the Pontus Euxinus, which dashed against each other until they became fixed when the Argo made its way between them. See ARGO-NAUTS.

**SYMPOSIUM** (Lat., from Gk. Συμπόσιον, banquet). 1. A philosophical treatise by Xenophon, discussing the nature of love and friendship, and depicting the character of Socrates, who is one of the speakers. 2. A dialogue by Plato, intended probably as a corrective of the similar work of Xenophon. Its subject is the nature of love, and Socrates and Alcibiades are among the speakers.

**SYMPTOM** (from Gk. σύμπτωμα, *symptōma*, chance, mischance, symptom, from συμπίπτειν, *sympiptein*, to fall in with, happen, coincide). A medical term denoting a phenomenon by which a physician judges of the presence of disease. A group, or syndrome, of symptoms enables the physician to judge directly of the nature of and to identify the disease, or to decide upon the lesions or morbid tissue changes, and then determine what disease is present. This decision is called a diagnosis. (See PATHOLOGY.) Symptoms are objective, including those perceived by the physician and found upon examination, such as heart murmurs, rise of temperature, etc.; or subjective, including those perceived only by the patient, as pain, ringing in the ears, etc. Symptoms are pathognomonic when they are sure signs of a certain disease.

**SYMPTOMATIC ANTHRAX.** See BLACK-LEG.

**SYNÆSTHESIA**, sī'nēs-thē'sī-ā. Secondary or concomitant sensation. The term covers those abnormal cases in which a stimulus arouses not only its appropriate sensation but also a concomitant sensation or image. The most frequent form is colored hearing (q.v.). Others are colored taste, colored pain, pressure, and temperature; one case of tasted sound (gustatory-tactual audition) has been reported. The theories are of two kinds: psychological and physiological. The former include theories based on normal associations, or associations through the intermediation of a sense feeling.

The latter posit some abnormal condition in the brain, particularly in the cortex. The facts that colored hearing is an hereditary trait, and that synæsthesias are more frequent in the child and the adolescent than in the adult individual, make the physiological view the more plausible. Consult references under COLORED HEARING.

**SYNAGOGUE** (Gk. συναγωγή, *synagōge*, assembly, from συνάγειν, *synagein*, to bring together, from σύν, *syn*, together + αἰνέειν, *agein*, to lead; corresponding to Heb. *kēnēsēth*, assembly, and *beth ha-keneseth*, the house of assembly). The name used in Greek cult societies to designate a "meeting" for religious purposes as well as a "society," but also in general to denote a "gathering," such as a symposium, or an "association," such as a barbers' union; in the Greek version of the Pentateuch as a translation of 'edah, "congregation" in distinction from *kahal*, which is rendered ἐκκλησία, *ecclesia*; in the New Testament as a designation of the Sabbath assembly (Acts xiii. 43) and of the houses where the Jews assembled for worship (Acts xv. 21); in Philo, Josephus, and other writers as a synonym of προσεύχη, *proseuchē*, house of prayer; and in modern times as a title of a Jewish house of worship. Jews who lived in foreign lands and did not feel free to build regular temples, as those of Elephantine (see ELEPHANTINE PAPYRI), Leontopolis (see ONIAS'S TEMPLE), and Shechem (see SAMARITANS) did, must at a comparatively early time have assembled in specially designated houses for worship without the sacrifice of animals on the Sabbath. But the earliest known reference to such a house occurs in an inscription recording the dedication of a proseuche in the time of Ptolemy III and Berenice (c.230 B.C.). Josephus mentions a synagogue or temple in Antioch in the time following Antiochus Epiphanes (*Bell. Jud.*, vii, 3, 3). Whether Ps. lxiv. 8 refers to synagogues is doubtful, and there is no allusion in 1 or 2 Maccabees to the burning of synagogues in Jerusalem in the time of Antiochus IV. According to Acts vi. 9 there were synagogues in Jerusalem of the Libertines, i.e., probably the "freedmen," descendants of the Jews sent by Pompey as slaves to Rome and then emancipated, the Cyrenæans, Alexandrians, Cilicians, and Asiatics (from Asia Minor). In the time of Jesus there were synagogues in Nazareth and in Capernaum; the latter, at Tell Hum, was excavated in 1905 by the Deutsche Orient-Gesellschaft. The synagogues of Galilee, described by Renan, were apparently somewhat younger; the best preserved is that of Kafr Bir'im, those of Kasyun come from the time of Septimius Severus. Philo found synagogues in Rome, Paul many in all parts of Asia Minor, Macedonia, and Greece. Babylonian synagogues are mentioned in the Talmud; they are outside of such cities as Nehardea and Mahuza, and do not seem in any instance to be earlier than the Christian era. In 1883 the ruins of an ancient synagogue were found at Hammam Lif near Carthage.

Synagogues were erected from the common funds or free gifts of the community and supported by taxes and donations. Regarding their architecture, in Palestine the Græco-Roman model of public buildings was followed, though with some essential modifications. Abundant ornamentation was an exterior and interior feature. The larger synagogues were divided by rows of pillars into several aisles; some had porticoes in front. In later times in Europe the

Romanesque style was adopted, and now Moorish architecture is frequently the model. Little is known of any special law respecting the construction of these buildings, save that the faces of the worshipers should be directed towards Jerusalem; that, in accordance with the verse in the Psalms, there should be a slight descent of a step or two on entering; that the building should stand, if feasible, on slightly elevated ground, or be somehow made visible from afar. Within at the extreme eastern end was the holy ark or chest (*tēbāh*), containing several copies of the Pentateuch, from which the periodical readings were chanted. In front of this was the stand of the public reader of the prayers, not far from which was suspended the everlasting lamp. On a raised platform in the middle of the synagogue was the place of the reader or preacher. The women (not counted as members of the congregation) sat separated from the men.

The affairs of the synagogue were administered by a board of ancients or elders, at whose head stood a chief or principal (*Rōsh ha-kene-seth*, *archisynagogos*). The chief was not a scribe, though taking rank immediately after the scribes. The officiating minister, whose office it was to recite the prayers aloud, was called *shēliach shībūr* (messenger of the community). The *chazzān* had general charge of the sacred place and its books and implements. He had to present the scroll to the reader, received it back after the reading was finished, rolled up the scroll and deposited it in the chest, and it was he who announced the advent of the Sabbath or of a holy day from the roof of the synagogue with a thrice repeated trumpet blast. During the week days he had to teach the children of the town or village. He had to be initiated by a solemn imposition of hands. The name of *chazzān*, however, at a later period, came to designate the officiating minister, and it has retained that meaning until this day. Almoners or deacons, who collected or distributed the alms, possibly the same as the *batlanīm* (idle men), whose office in relation to the synagogue cannot be exactly determined, but who had always to be ready for the purpose of making up the requisite number of 10 worshipers were further attached to the general body of officials. The third, sixth, and ninth hours of the day were the times appointed for daily worship; the more special days were Monday and Thursday, when the judges sat and the villagers came to town, and Saturday, on which the forms of some of the prayers were altered according to the occasion.

The reading from the Scriptures, though in Hebrew, was coupled in the synagogues of Palestine and Babylonia with a translation or paraphrase in the current Aramaic idiom, and presumably in the synagogues of Egypt a Greek translation was employed, but the chief prayers were always pronounced in Hebrew, though the Talmud admits the use of other languages in worship. Besides the prayers and the readings, a feature of early synagogue worship was the exposition of the law or of the lesson of the day by a competent person. In course of time a more elaborate liturgy developed. The oldest complete ritual, known as *siddur* (arrangement), dates from the year 880 A.D. and was compiled by a Rabbi Amram. In the liturgy as finally evolved two distinct elements are discernible: the *Shema'* (Hear, O Israel, etc.),

being a collection of the three passages (Deut. vi. 4-9; xi. 13-21 and Num. xv. 37-41) expressive of the unity of God and of His government over Israel, put together without any extraneous addition; and the *Tēphillāh*, or prayer, consisting of a certain number of supplications, with a hymnal introduction and conclusion, followed by the priestly blessing. The single portions of this prayer gradually increased to 18, and the prayer itself received the name of *Shēmōneh 'esrēh* (eighteen). For a long time the prayers were recited only by the reader, the people joining in silent responses and amens. These readers by degrees—chiefly from the tenth century—introduced occasional prayers of their own, and ultimately religious doctrine, history, saga, angelology, and mysticism, interspersed with biblical verses, are found put together in a mosaic of the most original and fantastic, often grand and brilliant, often obscure and feeble kind. The ritual differed in different countries. At the beginning of the nineteenth century a movement began in Germany for the reform of the ritual and gradually spread to other countries. At first the changes consisted in the shortening of certain prayers, the omission of others, and the introduction of German, English, or French by the side of the Hebrew.

The synagogues contributed more than anything else to the steadfast adherence of the people to their religion and liberty as long as there was any possibility of keeping both intact. At the same time they gradually undermined the priestly and aristocratic element that gathered around the temple, its gorgeous worship and kingly revenues. Their importance as a place of instruction as well as a place of worship was of profound influence on the development of Judaism. Both primary and advanced instruction in the Scriptures and subsequently in Talmudic literature was given in the synagogue, and in the early centuries of the Christian era legal decisions were likewise announced there. The synagogue could also be used as the place of mourning for prominent members of the community, and there are instances on record of the use of synagogues for political gatherings. In Babylonia travelers were accommodated in the synagogue and ate their Sabbath meals there. In view of these various uses to which the synagogue was put, it is not surprising that it became in the Middle Ages the centre of the religious and intellectual life of the Jews and in a measure of their social life as well. The "reform" movement within Judaism as well as the extension of the intellectual interests of the Jews has resulted in narrowing the influence and scope of the synagogue to purely religious affairs, though in orthodox Jewish communities in eastern Europe and in the Orient the former status of the synagogue is still in large measure maintained.

Abrahams, *Jewish Life in the Middle Ages* (ib., 1896); Emil Schürer, *Geschichte des jüdischen Volkes im Zeitalter Jesu Christi II* (4th ed., Leipzig, 1907; Eng. trans. of 1st ed., New York, 1896). For the ritual: Leopold Zunz, *Der Ritus synagogalen Gottesdienstes, geschichtlich entwickelt* (Berlin, 1855-59); Leopold Löw, "Der synagogale Ritus," in *Gesammelte Schriften*, vol. iv (Szegedin, 1889); L. M. Dembitz, *Jewish Services in Synagogue and Home* (Philadelphia,

1899). A complete English translation of the Portuguese ritual may be found in Lesser's prayer book (Philadelphia, 1845); and a translation of the German ritual in Sachs's *Machsar* (Berlin, 1866). Consult also: "Synagogue" and "Synagogue Architecture," in *The Jewish Encyclopædia* (New York, 1905); M. Friedlander, *Synagoge und Kirche in ihren Anfängen* (Leipzig, 1908); H. Fiebig, "Synagoge," in *Die Religion in Geschichte und Gegenwart* (Tübingen, 1913); G. Elbogen, *Geschichte des jüdischen Gottesdiensts* (Berlin, 1915).

**SYNAGOGUE, THE GREAT** (Heb. *ha-kenceth ha-gedōlah*). A designation of the assembly described in Neh. viii-x. The 85 elders enumerated in Neh. x. 2-29 were supposed to have formed a body to whom the Law was transmitted from the prophets and by whom it was handed down to Antigonus of Soko (*Pirke Aboth*, i, 1 ff.). Tradition afterward increased their number to 120. Their labors were thought to have been completed in one generation, but according to the faulty chronology of later Jewish writers this generation covered the entire period from the return of the exiles to Alexander. Hence Zerubbabel, Jeshua, Nehemiah, and Mordecai are regarded as "men of the Great Synagogue" as well as Ezra, the signers of the covenant, and Simon the Just. They are said to have written Ezekiel, Daniel, Esther, and the Minor Prophets, which probably means that they edited and gave recognition to these books. The distinction between *midrash*, *halakoth* and *haggadoth* is ascribed to them, as well as the introduction of the Purim festival and the institution of the Shomoneh 'Esreh and the other prayers and benedictions. The spirit and tendency of their work is expressed in the sentence ascribed to them in *Pirke Aboth*, i, 12: "Be careful in pronouncing opinion; have many pupils; put a fence about the Law." When the chronological error was perceived, the Great Synagogue was conceived of as a permanent institution during the Persian period, and many more functions were assigned to it. Some sort of a council dealing with the sacred text and the ritual may indeed have existed from the time of Ezra, but Kuenen has shown that the conception of the Great Synagogue grew out of the account in Neh. viii-x. Löw's suggestion that the idea came from the assembly described in 1 Macc. xiv. 25 ff. is less plausible. The notion that the Great Synagogue fixed the canon does not seem to appear before Elias Levita in the sixteenth century. Consult: A. Kuenen, *Over de mannen der groote synagoge* (Amsterdam, 1876); D. Hoffmann, "Ueber die Männer der Grossen Versammlung," in *Magazin für die Wissenschaft des Judenthums*, vol. x (Berlin, 1883); S. Bacher, in *The Jewish Encyclopædia* (New York, 1905); Emil Schürer, *Geschichte des jüdischen Volkes*, vol. ii (4th ed., Leipzig, 1907; Eng. trans. of 1st ed., New York, 1896); R. T. Herford, *Pharisaism* (ib., 1912).

**SYNAGOGUE OF THE LIBERTINES.** See **LIBERTINES**.

**SYNCHRONDROSIS.** See **JOINT**.

**SYNCHRONIZER.** A device used in electric-power stations for indicating when an alternating-current generator is operating at the same frequency as others with which it is desired to connect it in parallel in the same circuit. Also for determining whether the voltages

of two circuits are in phase with each other. It is called also a synchronism indicator or synchroscope, although this last term is applied to an instrument that shows whether a generator that is to be synchronized is running too fast or too slow. One type of synchronizer consists of a small motor having its field windings connected to one of the generators to be synchronized and its armature to the other. By means of an arrangement of two armature coils, one of which has a reactance in its circuit, a rotating field is produced which causes the armature to move in one direction or the other by an amount depending upon the difference in phase between the two circuits and indicating by a pointer attached to the end of the armature whether the machine to be synchronized is running fast or slow. Another kind indicates synchronism by means of two incandescent lamps so connected between the two circuits as either to light up or remain dark when put in circuit between them. Consult K. W. E. Edgumbe, *Industrial Electrical Measuring Instruments* (New York, 1908); J. A. Haraden, "Operation and Installation of Switchboard Synchronism Indicators," in *General Electric Review*, vol. xvi (Schenectady, N. Y., 1913); C. M. Jansky, *Electrical Meters* (New York, 1913); N. E. Funk, "Operation of Frequency Changers," in *Transactions of the American Institute of Electrical Engineers*, vol. xxxii (ib., 1913). See **DYNAMO-ELECTRIC MACHINERY**.

**SYNCHRONOUS CONVERTER.** See **DYNAMO-ELECTRIC MACHINERY**.

**SYNCHRONOUS MOTORS.** See **DYNAMO-ELECTRIC MACHINERY**.

**SYNCHROSCOPE.** See **SYNCHRONIZER**.

**SYNCLINE** (from Gk. *συνκλίνειν*, *synklinein*, to lean together). A term used in geology for the structure formed by the bending of strata into a basin of downward fold, the limbs of the fold dipping towards each other and meeting at a line called the synclinal axis. Where the strata dip downward from all sides a peculiar type of syncline arises, known as a geologic basin; in this case the synclinal axis is reduced to a point. The syncline, structurally, is the complement of the anticline (q.v.). See **GEOROLOGY**.

**SYNCOPATION** (from Lat. *syncopatus*, p.p. of *syncopare*, to syncopate, from *syncope*, from Gk. *συνκοπή*, *synkopē*, a cutting short). In music, the joining together of two similar notes by means of a tie, so that the accent intended to fall on the second (strong beat) comes on the first (weak beat). The effect produced is that of contra-tempo. The following example is from Beethoven's overture "Lenora No. 3":

The effect of syncopation can also be produced by merely shifting the accent by means of *sforzando* marks, as in the scherzo of the *Eroica Symphony*:

The North American Indians made extensive use of syncopation, and in this were followed by

the Southern negroes. In fact, the music of nearly every savage or semicivilized nation shows traces of syncopated rhythm.

**SYNCOPE**, sín'kô-pé. See FAINTING; HEART, DISEASES OF THE.

**SYNCRETISM** (from Gk. συγκρητισμός, *synkretismos*, combination against a common enemy, from συγκρητίζειν, *synkretizein*, a word whose etymology is unknown). A term used: (1) according to Plutarch, in ancient times, politically, to designate the custom of the Cretans or others of disregarding all internal dissensions whenever a controversy with a foreign country occurred; (2) in the sixteenth century, philosophically, to denote the efforts made to reconcile opposing systems; (3) in the seventeenth century, theologically, first by Pereus in his *Irenicon*, and afterward to describe the views of Calixtus and his followers, who sought to heal the schism in the church by making the traditions of the first five centuries of equal authority with the Bible, and by adopting the Apostles' Creed as the common basis of all Christian denominations and a sufficient definition of true Christianity; (4) most frequently, of the efforts made in ancient times, especially in the second to the fourth century A.D., to simplify religion by identifying various gods or various aspects of the same god. In the teaching of the Neoplatonists syncretism did much to encourage belief in a single god. See HENOTHEISM.

**SYNCRETISM**. See ETYMOLOGY, FIGURES OF. **SYNCRETISTIC CONTROVERSY**. See CALIXTUS, GEORG.

**SYNDIC** (from Lat. *syndicus*, from Gk. σύνδικος, *syndikos*, advocate, public officer). A name which has at different times and in different countries been given to various municipal and other officers. In Geneva the chief magistrate was formerly called the syndic. The syndics of cities in France, under the old régime, were officers delegated by the municipality as agents or mandataries; the various trading companies in Paris and the university had also their syndics; and in the University of Cambridge the same name is applied to members of special committees of members of the senate appointed by grace from time to time for specific duties. In Italy the mayors of towns are called syndics.

**SYNDICALISM**. A form of revolutionary labor unionism, deriving its name from the general term *syndicat* applied to the labor union in France, where the movement especially flourishes. Syndicalism is opposed, on the one hand, to old-line trade unionism, and on the other hand to political socialism. Its ideal is the direct assumption by organized bodies of workers of full control over all industries. It does not work for collectivism, or the ownership and operation of industries by the state, but in so far as its programme is defined it proposes to vest control of the mines in the mine workers' organization, of the railways, in the railway workers' union, etc. Syndicalism has no faith in reform through parliamentary action, nor does it have faith in revolutionary insurrections. It seeks first to wean the capitalist from his interest in property through curtailment of profit by means of strikes, boycotts, and sabotage (q.v.), and finally to overturn the weakened capitalistic system through the general strike.

Revolutionary syndicalism in France may be said to date from the labor congress of Marseilles in 1892 when Aristide Briand offered a resolution condemning insurrection and urging the

general strike as a means of destroying the existing economic order. The motion was lost, but was carried in the congress of Nantes in 1894. In 1897 antagonism to parliamentary socialism gained dominance over the movement. At the Congress of Limoges in 1895 a permanent organization had been created under the name of Confédération Générale du Travail, a federation of national and regional unions, which was reorganized and strengthened in 1902. Since 1906 the Confédération has sought to extend the industrial principle of unionism at the expense of the trade principle. Trade unions proper are no longer admitted to the Confédération.

The strength of revolutionary syndicalism in France is not easily estimated. The membership of unions affiliated with the Confédération Générale du Travail exceeded half a million in 1914. But a majority, probably, were out of sympathy with the more radical points in the syndicalist programme. The control of the extremists is largely due to the peculiar plan of representation, whereby a local unit having thousands of members is placed on an equal footing with one having only a few score. Thus the larger and more conservative unions are without proportionate representation.

In Italy a similar movement was organized in 1906 in the Confederazione Generale del Lavoro, but it fell under the control of the parliamentary Socialists. In 1912 a syndical union, representing the economic movement as opposed to the political, was organized. This union lays claim to more than 100,000 adherents. Syndicalism has also made headway in Spain and Greece, and there are sporadic traces of it in Latin America. In England a development in the same direction set in with the New Unionism of 1885, which sought especially to organize the unskilled workmen, such as the dockers, gasworkers, seamen, and discarded the benefit features of the older trade unions. At first the New Unionism sought to attain its ends through political means, but by 1910 had lost faith in parliamentary action and, like French syndicalism, reposed its hopes in direct action, boycotts, and strikes and ultimately in the general strike. The nearest analogy to syndicalism in the United States is the Industrial Workers of the World (q.v.). Consult: Guy-Grand, *La philosophie syndicaliste* (2d ed., Paris, 1911); Sir Arthur Clay, *Syndicalism and Labour* (New York, 1911); J. R. Macdonald, *Syndicalism* (London, 1912); J. G. Brooks, *American Syndicalism* (New York, 1913), containing a bibliography. See LABOR ORGANIZATIONS; TRADE UNIONS.

**SYNECDOCHE**, sí-nék'dô-ké. See RHETORIC, FIGURES OF.

**SYNECOLOGY**. That branch of the science of plant ecology that relates to plants as they are associated in communities. See ECOLOGY OF PLANTS.

**SYNERGISM** (from Gk. συνεργία, *synergia*, coöperation). The name given to a doctrine of theology which teaches that in the work of conversion the will of man is not wholly passive, but can coöperate, through consent, with the Divine Spirit. In the time of the Reformation Melancthon (q.v.) and his school were inclined to this view, while the strict Lutherans opposed it and charged its advocates with favoring Pelagianism (q.v.). In 1557 and later the question was hotly discussed, Pfeflinger and Strigel taking the lead on the Synergistic side, Flacius

and Amsdorf (q.v.) on the opposite. The Wittenberg divines in general favored the doctrine, the Mansfield divines opposed it. Finally it was condemned in 1580 in the third article of the Formula of Concord. See CONCORD, Book of.

**SYNE'SIUS** (Lat., from Gk. *Συνέσιος*) (c.370-?). A Neo-Platonic philosopher and Christian bishop. He was born at Cyrene in Lybia, and studied philosophy in Alexandria, under Hypatia, to whom he was ever warmly devoted. His life illustrates the combination of Neo-Platonism and Christianity characteristic of the fourth century. Synesius was made Bishop of Ptolemais in 410, against his own desire, and with the apparent stipulation that he should not be obliged to give up his wife or his philosophy, but he administered his see with fidelity. Neither the time nor the place of his death is known. Synesius' writings include about 150 letters; *Egyptian Tales*, or on Providence, a sort of historical allegory of the providential government of the world; a defense of the philosophic life, *Dio* (after Dio Chrysostom); a humorous work, called *Praise of Baldness*, suggested by Dio's *Praise of Hair*; and ten *Hymns*, partly pagan and partly Christian. His character is well portrayed in Charles Kingsley's *Hypatia*, in which Synesius figures. His works are in Migne, *Patrologia Graeca*, lxvi. Consult: H. V. M. Druon, *Études sur la vie et les œuvres de Synésius* (Paris, 1859); R. Volkmann, *Synesius von Cyrene* (Berlin, 1869); A. Gardner, *Synesius of Cyrene* (London, 1886); W. S. Crawford, *Synesius the Hellene* (ib., 1901); T. R. Glover, *Life and Letters in the Fourth Century* (Cambridge, 1901).

**SYNGE**, sîng, JOHN MILLINGTON (1871-1909). An Irish dramatist, born at Newtown Little, near Rathfarnham, and educated at Trinity College, Dublin. From 1892, the year of his graduation from college, until a decade later, he studied music in Germany and languages, for which he had a gift, in Germany, France, and Italy. He rambled about, settling finally at Paris, where he devoted himself to French literature, and sought to make himself a literary critic. During the ten years referred to he frequently returned to Ireland, and, after 1899 and until 1903, he made annual sojourns in the Arran Islands, with a view to following up the suggestion made by his friend William Butler Yeats (q.v.) in 1899 that he abandon criticism and write of the primitive life of the Arran Islanders which had never been brought into literature. In 1903 he took up his abode in Ireland, and devoted himself enthusiastically to the interests of the Abbey Theatre, Dublin, becoming one of its three literary advisers. Fortunately Synge had a small competence, which made him free to study, and to roam in Ireland and on the Continent as his restlessness prompted. He is beyond question the best of the dramatists of the Irish Literary Revival (see IRISH LITERATURE, *Irish Literature in English*), as his *Playboy of the Western World* (produced 1907), and his tragedy, *Deirdre of the Sorrows* (produced 1910), attest; and the contention that his *Playboy* is the best comedy in English since Sheridan may eventually be justified. In addition he wrote the excellent short plays, *The Shadow of the Glen* (produced 1903), *Riders to the Sea* (produced 1904), *The Will of the Saints* (produced 1905), and *The Tinker's Wedding* (produced 1909). Primarily a dramatist, Synge

wrote also, and notably, sketches of social types and of the manners and customs of the Arran Islands, of Wicklow, and of West Kerry; and a little sheaf of poems which, if not important as poetry, are a sidelight on their author's personality. Everything of Synge's which his literary executors thought worthy of inclusion is contained in his *Works* (4 vols., Dublin, 1910). Consult: W. B. Yeats, *J. M. Synge and the Ireland of his Time* (New York, 1911); P. P. Howe, *Synge: A Critical Study* (London, 1912); Francis Bickley, *Synge and the Irish Dramatic Movement* (Boston, 1912); Maurice Bourgeois, *Synge and the Irish Theatre* (London, 1913), the most substantial study; John Masefield, *John M. Synge* (New York, 1915).

**SYN'OD** (Lat. *synodus*, from Gk. *σύνωδος*, assembly). A term applied almost exclusively to ecclesiastical assemblies convoked for the discussion and decision of ecclesiastical affairs. Synods or church councils are of five kinds: ecumenical, general, national, provincial, and diocesan or local. By the law of the Roman Catholic church the decrees of a national or provincial synod must be submitted to the Pope, and unless confirmed by him, or suffered to pass for two years without condemnation, are not held valid. The term "synod" also describes courts in the Presbyterian system of church government which rank above the presbytery, and are either subordinate to a General Assembly or themselves constitute the supreme court of the church. The courts above the classes in the Dutch and German Reformed churches are called synods. In the organization of the Lutheran churches the synod is the highest representative body. Two of the Eastern churches have preserved the synod. The Holy Governing Synod of All the Russias is the highest ecclesiastical authority of the Russian church. The orthodox national church of the Kingdom of Greece is also governed by a synod of archbishops and bishops independent of the jurisdiction of any patriarch. For other conciliar organizations, see COUNCIL.

**SYNODIC** (Lat. *synodicus*, from Gk. *συνωδικός*, *synodikos*, relating to a conjunction, from *σύνωδος*, *synodos*, assembly). In astronomy, the synodic period is the time which elapses between two successive conjunctions (q.v.) of a planet with the sun, as seen from the earth. In the case of the moon, the synodic period is therefore the time elapsing between two successive new moons. See MOON.

**SYN'OD OF DORT.** See DORT, SYNOD OF.

**SYNODS OF EPHESUS.** See EPHESUS, COUNCILS OF.

**SYN'ONYM** (Fr. *synonyme*, Lat. *synonymum*, from Gk. *συνώνυμον*, *synónymon*, having the same meaning, from *σύν*, *syn*, together + *ὄνομα*, *onoma*, name). A word which nearly coincides in meaning with another, as clear, transparent; bright, limpid; fair, cloudless; lucid, perspicuous; patent, obvious; visible, evident. There is in most cases a slight individual shade of meaning in each synonym. Development of synonyms is one first of convergence and then of divergence, but the meanings are originally quite distinct. In semasiological evolution, however (see SEMASIOLOGY), the particular words which tend to become synonymous overlap in meaning. This may then continue till the words become identical in meaning. In this case the result is suppression of one of the terms, either complete or partial. The latter process gives the so-called composite inflection, illustrated in such English

verbs as *am*, *be*, *was*, or *go*, *went*, in which verb roots originally distinct have coalesced. But, if synonyms do not become identical, they tend to become so specialized in meaning with respect to each other that they not only retain their original distinctions, but frequently develop others. The main stylistic use of synonyms is to give variety and accuracy of diction.

Lyon, *Eberhards synonymisches Handwörterbuch der deutschen Sprache* (17th ed., Leipzig, 1910).

**SYNOVIAL MEMBRANE and FLUID** (from Neo-Lat. *synovialis*, from *synovia*, lubricating fluid secreted by a synovial membrane, so called because it resembles the white of an egg, from Gk. *σύν*, *syn*, together + Lat. *ovum*, egg). In every joint in which a considerable range of motion is required, the osseous segments (or contiguous extremities of bones) are separated by a space, which is called the cavity of the joint. The end of each of the bones entering into the composition of the joint is incrustated by a layer of articular cartilage adapted to its form, and the entire cavity of the joint is lined by a delicate membrane, which is termed the *synovial membrane*, which secretes a peculiar viscid matter, termed *synovia*, or *synovial fluid*, for the purpose of lubricating the inner surface. A synovial membrane is a closed sac, like the pleura, for example, with an attached and a free surface, the latter being smooth and moist. The minute structure of a synovial membrane is much the same as that of serous membranes elsewhere. (See **HISTOLOGY**.) A very simple form of synovial membrane—anatomically known as a *bursa*—is employed to facilitate the gliding of a tendon of a muscle or of the integument over a projection of bone. It consists of a sac connected by areolar tissue with the neighboring parts, and secreting a fluid in its interior. These sacs are sometimes prolonged into *synovial sheaths*, which surround long tendons, such as those of the flexor and extensor muscles of the fingers and toes. In *felon* (q.v.), when inflammation extends to one of the sheaths, and gives rise to the formation of adhesions, the motion of the inclosed tendon is destroyed, and a permanently stiff finger is the result. See **SYNOVITIS**.

The synovial fluid consists of water holding in solution mucin, albumen, fat, and inorganic salts.

**SYNOVITIS** (Neo-Lat., from *synovia*). Inflammation of a synovial membrane. Although inflammatory processes involving joints frequently start in an inflammation of the synovial

membrane, they rarely confine themselves to this membrane, but involve surrounding tissues. For this reason (especially in discussing the pathology of joints), the term "synovitis," which properly means inflammation of the synovial membrane only, has been to some extent displaced by the term "arthritis," which signifies inflammation of the joint in general, including the synovial membrane.

**Acute Arthritis** is usually an exudative inflammation and may be serous, sero-fibrinous, or suppurative. In serous arthritis there is congestion of the synovial membrane with a serous exudate into the joint cavity. With the subsidence of the inflammation the serum may be absorbed and the joint return to normal condition, or, becoming infected, may pass on to suppuration. The acuteness of the condition may pass off and the joint go on to a chronic inflammation. In sero-fibrinous arthritis there is in addition to the serum more or less fibrin in the joint cavity. Suppurative arthritis is an infectious condition due to the presence of bacteria. The exudate is purulent, while the synovial membrane is usually thickened, dull, and infiltrated with pus cells. Both simple (serous) and suppurative arthritis may accompany or follow some one of the infectious diseases, as, e.g., pyæmia, puerperal fever, gonorrhœa, diphtheria, and scarlet fever. Acute rheumatic arthritis or acute articular rheumatism is usually an exudative inflammation in which the exudate is serous in character and in which there is a successive involvement of different joints. Dry synovitis is characterized by a scanty exudate, and a deposit of fibrin on the serous surface, which usually evinces a very marked tendency towards organization, and consequently adhesions of contiguous surfaces with rapid ankylosis of the joint.

**Chronic Arthritis.** The most important forms of chronic arthritis are simple chronic arthritis, arthritis deformans, rheumatic arthritis, gouty arthritis, and tuberculous arthritis. In simple chronic arthritis there is a serous exudation into the joint cavity; the synovial membrane is thickened, pale, and rough. The exudate may be clear and watery, or cloudy from the presence of minute particles of fibrin or of lymphoid or endothelial cells. In that peculiar form of chronic inflammation of the joints known as arthritis deformans there is a combination of destruction of parts of the joint with new bone formation which leads to extensive deformities. The joints most commonly involved are those of the fingers, hips, knees, and feet. In gouty arthritis there is a deposit of urates in and about the joints. These deposits take place in the cartilages and in connective tissue and in the ligaments around the joints or even in subcutaneous tissue. The deposit may be in the form of crystals or of whitish concretions. In tuberculous arthritis the lesion is that of a tuberculous inflammation modified by the nature of the tissues in which the inflammation occurs. The tuberculous process frequently spreads to and involves the bone, resulting in extensive changes in the bones themselves.

**Tenosynovitis** is an inflammation of the synovial membrane sheathing the tendon of a muscle, and may follow an injury or any of the conditions provocative of arthritis. Treatment of synovitis or arthritis depends upon the cause. In the acute serous or serofibrinous varieties rest, alternate hot and cold affusion, extension of

the limb so as to separate the surfaces, and exercise with the joint immovable may be all that is necessary. In some cases passive motion is desirable, to break up adhesions, after prolonged rest in a splint. In some exudative, especially in suppurative, cases the joint is aspirated and the fluid drawn off. Rheumatic and gouty arthritis yields to the salicylates, alkalies, lithia salts, or other internal medicine used in rheumatism or gout. In tuberculous cases the joint is opened and the tuberculous nidus scooped out, or the joint is resected in some instances. Deforming arthritis usually leaves permanent deformities. Sometimes operative procedures, undertaken after the inflammation has ceased, will correct these deformities in part. Consult L. W. Ely, *Diseases of the Bones and Joints* (New York, 1914).

**SYNTAX.** See GRAMMAR; PHILOLOGY.

**SYNTAX, FIGURES OF.** Intentional deviations from the ordinary construction of words. The principal figures of syntax are: anaphora, the repetition of the same word or grammatical form at the beginning of successive clauses, as "*Without tumult, without arms, without injury the insurrection was quelled.*" Anastrophe, a transposition of words, as "*Rolled the thunder*" for "*The thunder rolled.*" Brachylogy, the use of a concise mode of expression, as "*The eye of a horse is bigger than an elephant,*" i.e., than (the eye of) an elephant. Chiasmus, a crosswise arrangement of words, where a second and corresponding set of words are stated in inverse order to those of the first set, as "*Begot by butchers, but by bishops bred.*" Enallage, the substitution of one part of speech, or of one inflectional form of a word, for another, as "*They fall successive and successive rise.*" Epanastrophe, the repetition of the end of a clause at the beginning of the next, as "*The mouse ran up the clock, the clock struck one.*" Epiphora, the repetition of a word at the end of successive clauses (the reverse of anaphora), as "*Lalius navus erat, doctus erat.*" Epizeuxis, emphatic repetition of a word, as

*"Alone, alone, all, all alone,  
Alone on a wide, wide sea."*

Hendiadys or hendiadyoin, the presentation of one idea by two coördinate words or phrases, as "*A couch strewn with purple and tapestry,*" i.e., with purple tapestry. Hypallage, the use of one case for another, the transference of an epithet from its proper subject to another, as "*Tyrrhenus tubæ clangor*" (Tyrrhenian clang of the trumpet) for "*Tyrrhæa tubæ clangor*" (clang of the Tyrrhenian trumpet). Hyperbaton, the transposition of words or clauses, as "*Valet atque vivit*" (he is well and alive) for "*Vivit atque valet*" (he is alive and well). Pleonasm, the use of superfluous words. Polysyndeton, pleonasm in the use of conjunctions (the reverse of asyndeton). Prolepsis, introduction of an epithet or a word before it is logically applicable, as "*I know thee, who thou art.*" Syllepsis, the agreement of an adjective or verb with only one of two or more words with which it is linked, as "*Rex et regina beati.*" Synesis, a construction of words according to the sense they convey rather than by strict requirements of grammatical rules, as "*Philip went down to Samaria and preached Christ unto them.*" Tmesis, the separation of parts of a word, as in Ennius' famous line, "*Saxo cere comminuit brum,*" or in "*The love of God to us ward.*" Zeugma, the use of a word in two or more connections, though it is applicable to only one of them. See ALLITERA-

TION; ELLIPSIS; PHILOLOGY, *Syntax*; RHETORIC, *FIGURES OF.*

**SYN'THESIS** (Lat. *synthesis*, from Gk. *σύνθεσις*, composition, combination). See ANALYSIS.

**SYNTHESIS, CHEMICAL.** The building up of compounds from their elements. The synthetic methods of chemistry are of the greatest importance in several respects. First, they may serve to test the correctness of analyses or even, in certain cases, replace analytical methods altogether. For example, if there were any doubt as to water being composed of eight parts of oxygen and one of hydrogen, or if water could not be analyzed at all, its exact composition could be demonstrated by causing oxygen and hydrogen to combine. In fact it was the synthesis of water by Cavendish that first indicated its chemical nature and exact composition. (See CHEMISTRY, historical section.) Secondly, synthetic methods may, and very often do, serve to reveal the complex chemical constitution of compounds of carbon. It is explained under CARBOXY COMPOUNDS (q.v.) that one of the basal principles employed in determining the constitution of compounds is the assumption, itself well founded on facts, that, when a given compound undergoes a moderate chemical change, the greater part of each of its molecules remains unaffected: an atom, or a group of atoms, may be replaced by another, but the linking of the remaining atoms is not changed. Thus, by the action of chlorine on acetic acid, the latter may be gradually transformed into monochloroacetic acid, dichloroacetic acid, and trichloroacetic acid, one, two, or three atoms of hydrogen in the molecule of acetic acid being replaced by one, two, or three atoms of chlorine; but the remaining atoms (carbon, hydrogen, and oxygen) are linked in the chloroacetic acids in the same manner as in acetic acid itself. On this principle the constitution of a compound becomes known if it is produced by synthesis from compounds of known constitution. In this connection it may be well to observe that the definition of the term "synthesis" must not be taken to mean the production of compounds from their elements directly. Thus, when it is said that ordinary alcohol can be produced synthetically, it does not mean that alcohol can be made by the direct union of carbon, hydrogen, and oxygen. The synthesis of alcohol consists of the following steps: carbon and hydrogen are caused to unite into acetylene (q.v.); acetylene is caused to unite with hydrogen into ethylene; ethylene is caused to unite with sulphuric acid to form ethylsulphuric acid; and the latter by reaction with water yields alcohol. The two compounds employed, viz., water and sulphuric acid, can also be made by starting with their elements; and so it may be said that ordinary alcohol can be made with nothing to start with but elementary substances, and this is what is meant by "the synthesis of alcohol from its elements." Finally, many synthetic processes have acquired great importance industrially. In 1868 Graebe and Liebermann built up by synthetic processes the substance called alizarin (q.v.), which occurs naturally in madder root and which gives the latter its chief value as a dyestuff. This artificial alizarin is now made on an enormous scale and has almost entirely displaced madder in dyeing and calico printing. In 1880 Adolf Baeyer accomplished the synthesis of indigo. Antipyrin, a substance much used in medicine, and saccharin, a substance several hundred times

sweeter than sugar, are entirely the products of synthesis.

Yet while most of the known carbon compounds can be produced synthetically, some of the most important organic substances, including the proteins and many carbohydrates, still remain unsynthesized, and hence but imperfectly understood, and must still be obtained ready-made from nature. The synthetic methods employed in the preparation of a large number of carbon compounds are mentioned under the special names of those compounds. Consult: P. E. M. Berthelot, *La synthèse chimique* (Paris, 1876; Ger. trans., Leipzig, 1877); Louise, *Synthèse d'hydrocarbures, d'acétones, d'acides, d'alcools, d'éthers et de quinones dans la série aromatique* (Paris, 1885); Karl Elbs, *Die synthetischen Darstellungsmethoden der Kohlenstoff-Verbindungen* (Leipzig, 1889-91); Theodor Posner, *Lehrbuch der synthetischen Methoden* (ib., 1903); Lassar Cohn, *Arbeitsmethoden für organisch-chemische Laboratorien* (2 vols., Hamburg, 1906-07). See CARBON COMPOUNDS; CHEMISTRY (historical section).

**SYNTHETIC GEOMETRY.** See GEOMETRY.

**SYNTHETIC MINERALOGY.** See MINERALOGY.

**SYNTHETIC RUBBER.** The efforts of chemists to synthesize rubber date from the discoveries of Bourchardt (1879) and Tilden (1882) that isoprene could be polymerized to form a substance that resembled rubber and that could be vulcanized. The hydrocarbon isoprene, or the closely related butadiene, has been obtained by various complicated chemical processes from starch, phenol, turpentine, and petroleum. The making of artificial rubber, while undoubtedly a chemical reality, has not reached the commercial stage, although in Germany tires for motor vehicles have actually been made. A method of polymerization that is rapid, cheap, and efficient will probably put synthetic rubber on the market. See SYNTHESIS, CHEMICAL.

**SYNTONIN** (from Gk. *σύντονος*, *syntonos*, stretched tight, from *σύντελειν*, *synteinein*, to stretch tight). A protein substance prepared by the action of dilute acids on the myosin of the muscles. The acid solution thus obtained is neutralized with alkali, and the precipitated syntonin is washed with a small quantity of water. Syntonin may be converted into a globulin probably identical with myosin, by dissolving in limewater, adding ammonium chloride, then neutralizing with acetic acid; from the solution thus obtained the globulin may be precipitated by adding the solution slowly to a large amount of distilled water. Syntonin is soluble in lime water and in dilute solutions of sodium carbonate, but not in acid sodium phosphate. It may be classed with the so-called metaproteins, and it is distinguished from other substances of the same class of proteins by its insolubility in acid sodium phosphate solution.

**SYPHAX**, *σιφάξ* (Lat., from Gk. *Σύφαξ*). A Numidian prince, who played a part in the Second Punic War, an enemy of Masinissa (q.v.).

**SYPHILIS** (from *Syphilus*, in the Latin poem entitled *Syphilus, sive Morbi Gallici Libri Tres*, by the Italian physician and poet Girolamo Fracastoro (1483-1553), a shepherd who was afflicted with the disease by Apollo as a punishment for offering homage to his King instead of to the god; of uncertain etymology, popularly explained as from Gk. *σῦς*, *sys*, hog, + *φίλος*, *philos*, loving, or, less plausibly, from *σύν*, *syn*,

with + *φίλος*, *philos*, loving), or LUES, or THE POX. A specific contagious disease peculiar to the human species, chronic in its course, and generally acquired during sexual congress. It is always due to contact with a syphilitic individual or with his secretions or discharges. Descriptions of syphilis are traced in the earliest writings, and it is asserted that indications of it are to be seen in the bones of prehistoric people, especially in South America, although Virchow maintained that these symptoms were not those of syphilis, but of arthritis deformans. (See SYNOVITIS.) In Chinese accounts scholars state that Hoan-Ti, who lived c.2637 B.C., mentions it, while in the earliest Indian records it is said to be found in the Ajwe-Veda of Suśrutas (400 A.D.). The Japanese historians described a disease several thousand years ago which is taken for syphilis. The Hebrews seem to have been familiar with it, and it is probable that many cases called leprosy were really syphilis. Hippocrates and his successors give a description of a disease which may be identical with syphilis, and Celsus mentions a disease which is somewhat similar to syphilis. Although it is probable that the malady existed in Europe as early as 1250 A.D., when Theodoric, a Dominican monk, wrote of the *malum mortuum* and recommended inunctions of mercury for its cure, its authentic and general recognition dates from a severe outbreak of the disease among the Spanish soldiers in the army of Charles VIII of France during the siege and following the occupation of Naples in 1495. It was known as the Neapolitan disease and as *morbis Gallicus*. Some scholars assert that this was the first appearance of syphilis in the Old World, it having been brought by Spanish sailors from America to Spain and thence to Italy. But this theory has lately been disproved by Sudhoff, whose researches and conclusions on the history of syphilis are now generally accepted as conclusive. The disease spread with frightful rapidity and virulence and during the following years was so widely disseminated as to be considered a form of plague. The armies of the various countries were nearly decimated, and no class of society escaped.

It was not at first recognized as a venereal disease. Its true nature appears to have been unsuspected at this time, as it was again a little previous to the time of John Hunter (q.v.), after whom was named the Hunterian or hard venereal sore. Hunter believed that there was but one venereal disease, that gonorrhœa, chancre, and syphilitic chancre were merely variations of the same constitutional affection. Nearly half a century later (1831) Ricord established the identity of gonorrhœa, but failed to distinguish between chancre and chancre. This was done by Bassereau in 1856. The severe epidemics of the fifteenth century have never been repeated, although syphilis has since prevailed with continually decreasing virulence. This is due in part to improved personal hygiene, better understanding of the disease, and rational treatment, but also doubtless to the fact that successive generations have transmitted a certain degree of immunity (q.v.) to their descendants. "It is believed that syphilis is a greater menace to the public health than any other single infectious disease, not even excepting tuberculosis," remarks Vedder. It is impossible to give adequate and correct statistical figures. The prevalence of syphilis and the impossibility of curbing the disease is not due to any misapprehension as

to its importance, but to our present social and sanitary conditions, which prevent successful legislation and treatment.

Syphilis is caused by a specific microorganism, the *Spirochæta pallida*, discovered in 1905 by Schaudinn and Hoffmann. The diagnosis of syphilis received a great impetus from the investigations of Wassermann and his followers. By means of the Wassermann reaction, Noguchi's modification of it, and the luetin test, syphilis can be diagnosed with great precision in all its different phases. The treatment also has been advanced by Ehrlich's work and his discovery of salvarsan (q.v.) and other arsenical derivatives, such as atoxyl (q.v.), soamine, and arsacetin.

Wassermann's reaction, the serum test for syphilis, depends on certain well-known phenomena of immunity (q.v.), which may be briefly stated as follows. If the washed red corpuscles of a sheep (taken as the antigen) are added to the warmed serum of a rabbit which has been previously immunized with washed red corpuscles of the sheep (this constituting the amboceptor) and fresh guinea-pig serum (the complement), thus forming what is known as a hæmolytic series, hæmolysis follows. This reaction was applied by Wassermann to the diagnosis of syphilis. The technic may be briefly stated: to the syphilitic antigen, consisting of an extract of syphilitic organs, are added fresh guinea-pig serum (the complement), the suspected serum, warmed rabbit serum (the amboceptor), and the washed red corpuscles of the sheep. The mixture is then incubated. If no hæmolysis occurs (by reason of the complement having been absorbed in the hæmolytic series), the antigen and the serum being homologous, the reaction is called positive. Noguchi has modified this technic by using human instead of sheep's corpuscles in the hæmolytic series. The luetin reaction consists in the intradermal injection of a killed culture of the spirochæte, and is particularly serviceable in diagnosing latent or hereditary syphilis, whereas the serum tests are more useful in identifying active syphilis. A number of other tests have been devised, notably the iodine test of Landau, for a description of which the reader must be referred to textbooks on this subject.

Syphilis requires for its transmission contact of the specific poison existent in the secretions or discharges of a syphilitic patient with an abraded surface of skin or with a mucous membrane. The blood is also capable of transmitting syphilis. Although the disease is as a rule acquired through sexual intercourse, syphilis inoscentium, or syphilis of the innocent, is of frequent occurrence. Physicians may become inoculated by contact with syphilitic patients, and innocent patients, on the other hand, may be infected, though rarely, by surgical and dental instruments. The saliva of syphilitic individuals carries the specific virus, and in this way inoculation may occur by kissing and the use of pipes, spoons, cups, pencils, etc. Great care is necessary when one member of a family is affected to prevent transmission of the disease to others, since in the familiar intercourse of relations great danger exists.

The manifestations of syphilis may be divided into three stages or phases, to which some authorities have added a fourth, viz., that of parasyphilis; but it must be remembered that these stages do not follow each other with any degree of regularity as to time or intensity, and certain phenomena may be absent or so slight as to es-

cape notice. The primary stage is that of the initial lesion, the Hunterian chancre, which appears as a rule within three weeks after infection. This consists, when fully developed, of an ulcer on an indurated base. After a period of quiescence, during which the primary sore heals—the so-called second incubation period, which lasts from four to eight weeks—there follows the secondary phase or stage of constitutional invasion. A rash, varying much in its characters, makes its appearance; small ulcers (mucous patches) appear on the mucous membranes, the lymphatic glands are enlarged, the throat is sore, there may be some fever, and there are the usual signs of an acute constitutional illness. This stage lasts for a variable period, depending on treatment and the violence of the invasion. Tertiary manifestations may not appear for years. The characteristic lesion of this stage is the gumma, which is essentially a soft elastic tumor composed of cells and fibrous tissue, with a tendency to ulcerate and break down. It may appear in any tissue of the body and in the breaking-down process may rapidly destroy considerable areas of tissue. The quaternary stage, or stage of parasyphilitic phenomena, appears late and is illustrated by such invasions of the cerebrospinal nervous system as tabes dorsalis and general paresis of the insane. In such diseases other factors besides syphilis enter into the pathology, and antisyphilitic treatment is successful only to a limited extent.

Congenital syphilis shows itself in many and curious ways. Children born of parents suffering from syphilis in the first or second stage may be infected with the disease. The infection may be derived from the father alone, the mother being healthy; or from the mother alone, the father being healthy; or from both father and mother. Or the mother may acquire syphilis after conception and convey it to the child in utero. A curious law, to which there seems to be no exception, is that, if a child inherits syphilis from its father, the mother being originally healthy, the infant may infect a wet nurse, but not its own mother, who is in some way protected against infection, although she may have shown no evidences of the disease. As a rule the effect of syphilis in the parents is to cut pregnancy short, with resulting miscarriages, premature or stillbirth. Children may be born alive, presenting lesions of any stage of the disease. In many cases the child is at birth apparently healthy, fat and plump, but in a few weeks develops a characteristic catarrh, commonly termed the snuffles, shows a rash, with ulcerations about the lips, genitals, and anus, and gradually wastes away until the face acquires a typical withered, shrunken, and aged appearance. Most of these children die in infancy.

The treatment and prophylaxis of syphilis is a matter of great importance, since there is no disease so widespread in its dissemination nor so potent in its influence upon the human species. Prevention depends on education in matters of sexual hygiene on the part of the public, elevation of the moral tone of the individual, and in segregation and inspection of prostitutes. The latter is practiced in many cities of the Old World, and attempts are constantly making towards the same end in the United States. Great ignorance prevails among the laity as to the nature, effects, and treatment of syphilis. The reliable remedies are still mercury and iodides; but these must be given with care and

under close observation and should be combined with tonic remedies, according to the needs of the particular case. Lay medication is apt to be ineffectual, if not dangerous. Mercury may be given by inunction, fumigation, hypodermically, or by the mouth. Excessive doses of mercury are likely to produce a series of very unpleasant symptoms (see MERCURY; SALVATION), and its unwise use in the hands of the ancient practitioners has resulted in a popular distrust of the drug. When these drugs are given properly, there is every reasonable prospect of a permanent cure. The time of treatment should extend over at least two and one-half years after all visible signs of the disease have disappeared, and marriage should be prohibited during this interval. The general health must be watched, and exercise in the open air, full diet, and appropriate tonics administered. In the syphilis of infants mercury is best given by inunction. Children somewhat older may take mercury in the form of gray powder in small doses. The two other drugs that seem to exert almost a specific effect in children are cod-liver oil and the iodide of iron. Ehrlich's salvarsan, while not without danger in itself, has added immensely to the possibilities of rapid cure in desperate cases and may be used in conjunction with the ordinary mixed treatment, above described. In the parasymphilitic affections salvarsan or neosalvarsan may be injected into the spinal canal, this being done through the medium of salvarsanized serum, viz., serum drawn from a subject who has shortly before been immunized by a dose of salvarsan. This serum is supposed to contain antibodies against the disease. Many brilliant cures have been reported, but the value of the method is not fully established. See HYGIENE, *Military Hygiene*. Consult: Fournier, *Syphilis and Marriage* (Eng. trans. by Morrow, New York, 1881); E. G. Ballenger, *Genito-urinary Diseases and Syphilis* (2d ed., Atlanta, 1913); F. H. Garrison, *An Introduction to the History of Medicine* (Philadelphia, 1914); Karl Sudhoff, *Aus der Frühgeschichte der Syphilis* (Leipzig, 1914); M. Nonne, *Syphilis und Nervensystem* (3d ed., Berlin, 1915).

**SYRA** (Lat. *Syrus*, from Gk. Σῦρος). An island in the Ægean Sea, belonging to the Cyclades and situated nearly in the centre of the group, 10 miles southwest of Tinos (Map: Greece, F 6). Area 31 square miles. It is for the most part barren and rocky, and its natural products are insufficient to support its population. It was the site of Hermapolis (q.v.), the capital of the nomarchy of the Cyclades and one of the chief commercial ports of Greece. Its modern importance dates from the time of the Greek war of independence, when it became the point of congregation of Greek refugees. Pop., 1896, 26,856.

**SYRACUSE** (Lat. *Syracuse*, from Gk. Συράκουσαι, *Surakousai*). Anciently the most famous and powerful city of Sicily, situated on the southeastern coast of the island, 33 miles south-southeast of Catania (Map: Italy, E 6). It was founded by Corinthian settlers under Archias, one of the Bacchiadae, near the end of the eighth century B.C. The original colonists seem at first to have occupied only the little isle of Ortygia, which lies near the shore, but with the growth of the city the population soon passed over to the mainland. This settlement was on Achradina, at the eastern end of a high triangular plateau, which lies north of the island. North

of the island lay the small harbor, while to the west was the great harbor, one of the best in Sicily. Ortygia was connected by bridges or a causeway with the mainland. The city consisted of Achradina, occupying the eastern end of the table-land and the adjacent coast, Tyche and Neapolis, to the west of Achradina, and of Epipolæ, still farther west, with the strong fort of Euryalus at the apex of the triangle. The colony rapidly rose to prosperity and was enabled to establish subcolonies of its own, Acræ (664 B.C.), Casmenæ (644 B.C.), and Camarina (599 B.C.). At first the government seems to have been in the hands of the descendants of the Dorian colonists, who were landowners employing a large body of serfs, seemingly Sicels. The commerce of the city brought, however, a large Demos of Greeks, who about 486 B.C. expelled the Gamori or ruling oligarchy and established a democracy. The Gamori were brought back in 485 by Gelon (q.v.), tyrant of Gela, who made himself master of Syracuse. He was a great ruler, and under him the city increased in size and wealth. He was succeeded by his brother Hiero I (q.v.) (478-467 B.C.), whose court became a literary centre. In 465 the democracy expelled his brother and successor Thrasybulus, and for 60 years a free and popular government was enjoyed under which Syracuse prospered greatly. The Sicels were reduced, and war was waged with neighboring states, till the island attracted Athenian intervention, only closed by the Peace of Hermocrates (424 B.C.). Renewed hostilities with Segesta (q.v.) led to the great struggle with Athens (415-413), in which Syracuse, aided by the Spartan Gylippus, annihilated the invading army and contributed not a little to the outcome of the Peloponnesian War. (See ALCIBIADES; GREECE, *Ancient History*; GYLIPPUS; NICIAS.) But a new power appeared on the stage—the Carthaginian—whose conquests in Sicily towards the close of the fifth century threatened the existence of Syracuse. (See CARTHAGE; SICILY, *History*.) The successful leadership of Dionysius the Elder (q.v.) enabled him to become tyrant of the city and make it the chief power of Magna Græcia and Sicily. He constructed docks and fortifications. His fierce and victorious war with Carthage (397 B.C.) raised the renown of Syracuse still higher. The reigns of Dionysius the Younger (q.v.) and of Dion (q.v.) were unsettled, but after the restoration of public liberty by Timoleon (343 B.C.) there was a brief season of tranquillity, during which the prosperity of the city rapidly revived. Under Agathocles (q.v.), however, the despotic form of government was again established (317 B.C.). This reign was marked by a war with Carthage, including an invasion of Africa, conducted with doubtful success. In 275 B.C. Hiero II (q.v.) was chosen general, and about 270 B.C. he assumed the title of King. He adopted the policy of alliance with Rome and preserved the independence of the state until his death in 216 B.C. His grandson Hieronymus joined the Carthaginians, and in consequence the city suffered a long siege, rendered famous by the devices of Archimedes, and was finally stormed and plundered in 212 B.C. by Marcellus.

Under the Romans Syracuse steadily declined, though it always continued to be the capital and first city of Sicily, and was made a colony by Augustus. Captured, pillaged, and burned by the Saracens (878), it sank into complete decay and is at present confined to its original limits,

Ortygia, which, however, is no longer an island, but a peninsula. The population of Syracuse, which is the capital of a province of the same name, was 27,352 in 1912, according to Baedeker. The mainland contains the chief remains of antiquity, which include a fine rock-cut theatre, a Roman amphitheatre, the great altar of Hiero II, the remains of the ancient fortifications, and the great Latomæ or quarries. The cathedral on Ortygia has been built around an ancient Doric temple: the columns of the temple form part of the church. The museum contains remains of the pre-Hellenic population, found in graves and caves in the neighborhood. In the southern part of the town is the famous fountain of Arethusa.

**SYRACUSE.** The fourth city in population of the State of New York, and the county seat of Onondaga County, 148 miles west of Albany and 149 miles east of Buffalo (Map: New York, D 4). It is situated at the mouth of Onondaga valley, 35 miles south of Lake Ontario, in an amphitheatre of hills. Area, 19 square miles.

Syracuse has superior facilities for transportation, steam railroads entering the city from ten directions, and canals from three. The Erie Canal pierces the heart of the city and gives water communication with Lake Erie and the Hudson River, and the Oswego Canal with Lake Ontario and the St. Lawrence. All steam railroad lines centring here are of two systems, the New York Central and Hudson River and the Lackawanna. Six interurban lines radiate from Syracuse. The street-railway system comprises 95½ miles of track, and reaches all sections of the city.

The chief residential streets are profusely shaded, presenting a parklike appearance. There are 38 public parks, ranging from small plots at street intersections to Burnet Park, on the hillside to the west, with more than 120 acres. Lincoln Park, a wooded height of 20 acres on the eastern border, commands a beautiful and extensive view of the city and its surroundings. The State Fair, under the auspices of the State Fair Commission, is permanently located in Syracuse.

The buildings of Syracuse University (q.v.) crown a commanding elevation and are among the most imposing edifices in the city. Other prominent public buildings are the city hall, the high school, costing \$400,000, the Carnegie library, the county courthouse, the Federal Government building, the State Asylum for Feeble-Minded Children, the House of Providence Orphan Asylum, the County Orphan Asylum, the Old Ladies' Home, and the five hospitals. The Carnegie library contains 150,000 volumes, the Court of Appeals Law Library, belonging to the State, 35,096 volumes, and the University Library, 96,000 volumes. The city also maintains a Museum of Fine Arts. The Onondaga Historical Society occupies its own building.

Industrially, Syracuse is fifth among the cities

of the State. Its establishments, according to the census of 1914, had \$63,957,000 invested capital, and a production valued at \$52,226,000. The city is noted for the number and diversity of its industrial establishments. In 1915 there were 760 plants, employing 25,000 persons. The chief articles manufactured are typewriters, automobiles and gears, candles, mince meat, china ware, clothing, agricultural implements, tool steel, furniture, cement, beer and ale, beds, caskets, carriages, wine presses, chemicals, drop forgings, elevators, fire escapes, incubators, mining machinery, safes, shoes, etc. The Onondaga Salt Springs are on the borders of Onondaga Lake. The manufacture of salt, from the brine pumped out of the springs, was formerly the main industry, but is now of minor importance. The Solvay Process Company's works, manufacturing soda ash and other products, and employing some 4000 men, are just outside the city limits on the west. With its many and varied manufactures, Syracuse has a large wholesale and export trade.

The government is vested in a mayor and common council, elected biennially. The comptroller and treasurer are chosen at the same time. The mayor appoints the heads of departments, including the city engineer, corporation counsel, and commissioners of public works, public safety, and charities. The schools are under the control of a board of education elected on a general ticket. In maintenance and operation the city spent, in 1914, \$2,976,000, the principal items being: schools, \$737,000, police department, \$128,000, fire department, \$225,000, and lighting, \$128,000. The assessed valuation of the city's property, real and personal, in 1915 was \$144,111,656. There are 100 miles of paved streets, principally of asphalt; 195 miles of sewers; and 234 miles of water mains. The water system is under municipal ownership and control. The water is obtained from Skaneateles Lake, 18 miles distant, and is conveyed by gravity to the city through 36-inch pipes. The plant cost \$5,000,000.

Pop., 1850, 22,271; 1880, 51,792; 1900, 108,374; 1910, 137,249; 1915 (State census), 146,587; 1920, 171,717.

The territory in which Syracuse is situated originally belonged to the Onondaga Indians. It was visited by the Jesuit missionary Father Isaac Jogues as early as 1642. By treaties in 1778 and 1795 the State bought a large tract containing the salt springs and formed from it the Onondaga Salt Springs Reservation, parts of which were subsequently sold to individuals. Syracuse proper was first settled about 1805, and was of little importance until after the completion of the Erie Canal, its population in 1820 being only 250. Until named Syracuse in 1819 it was known successively as South Salina, Bogardus' Corners, Cossitt's Corners, and Milan. It was incorporated as a village in 1825, and in 1847 absorbed Salina and was chartered as a city. It was prominent for its abolitionist sentiment preceding the Civil War, and was one of the chief stations on the Underground Railroad (q.v.). Here on Oct. 1, 1849, occurred the famous Jerry rescue, which did much to crystallize abolitionist sentiment in the North and arouse the animosity of the Southern planters. Consult Bruce, *Memorial History of Syracuse* (Syracuse, 1891).

**SYRACUSE, SOPHRON OF.** See SOPHRON OF SYRACUSE.

**SYRACUSE UNIVERSITY.** A coeducational institution for higher learning founded at Syracuse, New York, in 1870. Its college department is a continuation of Genesee College, which was conducted at Lima, New York, from 1851 to 1871. Its medical department is a successor of the Geneva Medical College (1835-72), which in part succeeded the Fairfield Medical College (1812-39). In 1915 the university comprised eight colleges: (1) the College of Liberal Arts, with classical and scientific courses leading to the degree of B.A. and B.S.; (2) the College of Fine Arts, with courses in architecture, belles-lettres, music, painting, art, and decorative design leading to the bachelor's degree in architecture, letters, music, and painting; (3) the College of Medicine, with a four years' course leading to the degree of M.D.; (4) the College of Law, with a three years' course leading to the degree of LL.B.; (5) the College of Applied Science, with courses in civil, electrical, and mechanical engineering leading to the corresponding engineering degrees; (6) the Teachers College, with fully equipped departments in pedagogy; (7) the College of Agriculture; (8) the New York School of Forestry. In the graduate schools the masters' and doctors' degrees are conferred. The university also maintains a school of oratory, a library school, a school of photography, and a summer school. In 1902 an observatory station of the United States Weather Bureau was established in connection with which lectures are given on meteorology and climatology. The university campus, containing about 100 acres, is situated on high ground and commands an extensive view of the surrounding country. Among the notable buildings on the campus are the Hall of Languages, occupied by several departments of the College of Liberal Arts, the Charles Demarest Holden Observatory, equipped with an 8-inch Alvan Clark telescope, the Administration Buildings, the John Crouse Memorial Hall, the Esther Baker Steel Hall of Physics, the Lyman Cornelius Smith College of Applied Sciences, the Carnegie Library, and the State Forestry Building. For athletic games there is a stadium which seats 20,000 spectators. The College of Medicine and the College of Law are situated in other parts of the city, but convenient to the main buildings of the university. The attendance in all departments, allowing for duplication, in 1914-15 was 4012. The faculty numbered about 300. The total resources are about \$5,000,000. The general library contains 100,000 volumes, including in this the historical library of Leopold von Ranke. The president in 1916 was James R. Day, S.T.D., LL.D.

**SYR-DARYA**, sēr-dār'yá, or **SIR-DARIA** (ancient *Jawartes*). A large river of Russian Turkestan, central Asia (Map: Asia, L 3). It rises on the north slope of the Tian Shan on the boundary of Chinese Turkestan, and flows in a general northwesterly direction until it enters the northeastern part of the Aral Sea after a course of over 1700 miles. Its upper course, known as the Narin, descends through a series of romantic gorges as a tumultuous mountain torrent, the fall being more than 3000 feet in less than 50 miles. It receives here numerous tributaries, but after making a long detour to the southwest around the highlands north of Ferghana, it enters upon the great arid lowland steppes, in which it receives

no more affluents, but decreases in volume by evaporation and by the use of large quantities for irrigation. Its course becomes here very sluggish. In the rainy season it overflows the surrounding country, and its low banks are in some places lined with extensive marshes. The discharge into the Aral Sea is less than half of the volume of the river in its middle course. The delta is marshy and shifting, and the depth on the bar is generally not more than three feet. From its lower middle course the river sends an arm across the desert to the southeastern end of the Aral Sea. This channel is now nearly dry, but probably indicates the former bed of the main river. The river is practically un-navigable in its lower course.

**SYR-DARYA**, or **SIR-DARIA**. A territory in northwest Russian Turkestan. Area, about 194,850 square miles (Map: Asia, H 4). The larger part consists of extensive sand wastes. The southeastern part belonging to the region of the Tian Shan Mountains rises in snow-covered peaks to an altitude of over 15,000 feet. The flat part of the territory is very scantily watered by the Syr-Darya and Amu-Darya (q.v.). The lakes are mostly salty. The settlements are found largely at the foot of the mountains, where the streams are utilized for irrigation. Wheat, silk, and cotton are the principal products. The nomadic inhabitants have extensive herds of cattle and sheep, and utilize the wool for the manufacturing of woolen products, besides exporting large quantities of the raw material to Russia and other parts of Europe. Horse breeding is carried on by the Kirghiz. The Central Asiatic Railway is the principal means of transportation. Pop., 1913, 1,989,000, consisting principally of Kirghizes and Sarts, the Russian forming only about 4 per cent of the total. Capital, Tashkend (q.v.).

**SYRIA**. Traditionally, the region lying between the Euphrates River and the Syrian Desert on the east and the Mediterranean on the west, and between the Alma Dagħ (the ancient Amanus) in the north and Egypt in the south. This region now forms a part of Asiatic Turkey (Map: Turkey in Asia, C 4). Mesopotamia, or at least a portion of it, is frequently designated as East Syria. Syria proper is now a vilayet of the Turkish Empire and is divided into six provinces—Jerusalem, Lebanon, Beirut, Aleppo, Syria, and Zor. It occupies approximately the area within the above boundaries. It, therefore, includes Palestine. Its area is 114,530 square miles.

Syria proper is traversed from north to south by a system of mountains connected with the Taurus in the north and in the south with Mount Sinai as well as with the important mountain chain of western Arabia. The loftiest section is the Lebanon district, comprising the range of the Lebanon proper, skirting the middle part of the Mediterranean coast attaining 10,050 feet in Dhahr el Kosdib, and the parallel Anti-Libanus reaching 9200 feet in Mount Hermon with the valley of Cœle-Syria, between them. Syria is in general a plateau of limestone, with the exception of the sandstone and granite hills of Edom. The plateau dips steeply to the Mediterranean. It is traversed north and south by a great rift valley, the displacement of the plateau level along lines of fracture, which, beginning at the Gulf of Akabah (of the Red Sea) in the south, extends under the

name of Wadi el Araba to the Dead Sea, thence north through the region of the Jordan to its sources, and beyond this through the Lebanon region, becoming narrower but widening again farther north, and finally reaches the sea at Antioch. This depression is over 400 miles long, and generally averages about 12 miles in width. It divides Syria (except in the north and north-east) into two long comparatively narrow stretches of table-land—the eastern and western. For the full description of the western, adjacent to the Mediterranean, see PALESTINE. The eastern strip merges into the Syrian Desert, and is sandy and bare, its elevated levels being dominated by the basaltic Jebel Hauran (6000 feet) situated east of Lake Tiberias. The Nahr el Asi (ancient Orontes), the Litany (Leontes), and many short streams flow into the sea on the west. The Jordan is the main feeder of the Dead Sea, whose surface is 1292 feet below that of the ocean. The principal affluents of the Jordan are the Yarmuk and Jabbok. In the east are a number of streams that die in the sands of the desert. There are several lakes besides the Dead Sea, the best known being Lake Tiberias (Gennesaret). The climate is that of the Mediterranean basin. At Beirut the mean annual temperature is 68° F.; at Jerusalem, 62.6° F. The rainfall is scanty, occurring in winter; Beirut having the heaviest with a rapid decrease south and east. The springs are short, the summers long, dry, and hot. Snow falls in winter and there is often almost severe cold. The flora is that of the Mediterranean region, the olive being prominent. Forests of conifers clothe portions of the western slope of the Lebanon. But small remnants survive of the famous cedars of Lebanon. In the east and south, however, the plant growth partakes of the scanty desert species. In the extreme north the date palm thrives. Of the wild fauna the lion has nearly disappeared, hyenas exist in some mountainous regions, and jackals abound. Gazelles are still met with. There are several species of venomous serpents, including the cobra. Formerly a land rich and highly productive, Syria is in modern times of very inferior agricultural and industrial significance. Fruits, grain, and vegetables are grown. The principal ports are Beirut and Jaffa. The Syrian Railroad has afforded an impetus to trade since 1895. The population is probably about 3,000,000. It is mainly Semitic in race. Mohammedans predominate, and Arabic is generally spoken. Bedouins and Arabs roam in the south and east. The Turks are few. The Christian population is considerable, the Maronites of the Lebanon region alone numbering over 100,000. There are many Jews in Palestine, where they form agricultural communities. The Mohammedan sect of the Druses (in the Lebanon region and the Hauran) has been prominent through its fierce hatred of Maronites. The chief towns are Damascus, Aleppo, Beirut, and Jerusalem.

**History.** About 1500 B.C. the kings of Egypt brought the greater part of Syria under their dominion. Their advance was opposed by the Hittites (q.v.), who were long dominant in northern Syria, and who spread also into the southern part of the country. The non-Semitic inhabitants were gradually amalgamated with the Semites among whom they dwelt, their speech becoming Semitic. About 1000 B.C. the Phœnicians were at the height of their power

and prosperity and the Hebrew Kingdom was firmly established. By this time the Hittites, whose state had become disintegrated into a number of principalities, had begun to feel the power of Assyria (q.v.). Under David and Solomon the Israelites extended their sway over a great part of Syria, subduing the southern Hittites, the Amorites, and other peoples, and conquering Damascus and other important cities. On the southern part of the coast the Philistine cities were united in a powerful confederacy. After the disruption of the Hebrew realm Damascus became the seat of a powerful independent Kingdom. This was destroyed in the second half of the eighth century B.C. by the Assyrians, who imposed their yoke upon the Philistine cities, and put an end to the Kingdom of Israel, while the Phœnician cities paid them tribute. About this time the last Hittite principalities were swallowed up by the same enemy. At the beginning of the sixth century B.C. Syria came under the rule of Babylon (q.v.), which was succeeded in B.C. 538 by that of Persia. In 333–332 B.C. Alexander of Macedon established his sway in Syria. At the close of the century upper Syria was appropriated by Seleucus, one of Alexander's generals, who founded Antioch as the seat of his Kingdom. The Ptolemies and the Seleucids (q.v.) contended for the possession of the rest of the country, which finally passed to the latter, whose realm, which embraced a large part of western Asia, came to be known as the Kingdom of Syria. Many Greek cities were founded by this dynasty. In 167–141 B.C. Palestine threw off the yoke of the Seleucids. In 64 B.C. Syria was made a Roman province and in the following year Judea was made tributary to the Romans.

In the third century A.D. the Kingdom of Palmyra, on the eastern borders of Syria, enjoyed a short-lived splendor. After the close of the fourth century Syria formed part of the Byzantine Empire, from which it was wrested in 634–636 by the Saracens. In 661 Damascus became the seat of the caliphs, but about a century later it was supplanted by Bagdad. In the second half of the eleventh century the Seljuks occupied the country. In 1099 the Crusaders took Jerusalem, which was made the capital of a Kingdom. At the same time was founded the Principality of Antioch. In the middle of the next century the Christian power in Syria was endangered by the assaults of Sultan Nureddin, whose seat was at Aleppo. In 1174–87 Saladin, Sultan of Egypt, wrested Syria from the successors of Nureddin and overthrew the Kingdom of Jerusalem. In the thirteenth century Khwarezmians and Mongols swept over Syria. In 1291 Acre, the last stronghold of the Christians on the Syrian coast, was taken by the Mameluke ruler of Egypt and Syria. In 1516 Syria was attacked and easily conquered by the Ottoman Turks. In 1831–33 Mehemet Ali (q.v.) of Egypt made himself master of the country, but was forced to relinquish it to the Sultan in 1840. In 1860 there were massacres of the Maronites by the Druses and a frightful slaughter of Christians at Damascus.

**SYRIAC APOCALYPSE.** See BARUCH, BOOKS OF.

**SYRIAC LANGUAGE AND LITERATURE.** The Aramaic dialect of Edessa and western Mesopotamia (see ARAMAIC), in which many literary productions have been preserved. Its name is derived from the Greek *Συρία*, which is either an abbreviation of 'Assyria', or a survival of the old designation Suri found in cuneiform inscriptions. Before the introduction of Christianity the natives of Mesopotamia called themselves Aramæans. Subsequently this term was used especially for the pagans, while the Christians were designed by Greeks and Persians as Syrians and seem to some extent to have adopted the name themselves. The Syriac language shows in its earliest documents a remarkably fixed type, and must therefore have been long spoken in Mesopotamia. Characteristic of this dialect are the *n* of the preformative in the imperfect of the verb and the loss of the determinative force of the emphatic ending *a* in the noun.

There was probably an extensive pagan literature both in Edessa and in Harran; but the story of Achikar (q.v.); an account of a water famine in 201 A.D. preserved in the Chronicle of Edessa; and the letter of Mara son of Serapion of the second and third century, published in Cureton's *Spicilegium Syriacum*, seem to be the only extant specimens. The translation of the Old Testament was probably made by Jews. It may belong to the first century A.D., though it was subsequently revised in some books with the aid of the Greek version. Two recensions of the oldest translation of the New Testament have been preserved in part in a Sinaitic manuscript of the Gospels and a Nitrian manuscript published by Cureton, containing fragments of the Gospels. This latter version may have been made in the latter half of the second century. A compilation of the four Gospels, called the *Diatessaron*, was made by Tatian (q.v.), or translated by him from a Greek work of the same kind, about 180. This diatessaron is lost and is known chiefly through Ephraem Syrus (q.v.); the Arabic translation of this work published by Ciasca seems to belong to the eleventh century, and has manifestly been made conformable to the standard text. Having been in use for a long time in the Mesopotamian churches, the diatessaron was supplanted by the Syriac Vulgate, or Peshita (see BIBLE, Versions), apparently in the fifth century, through the efforts of Bishop Rabbulas (died

435). 2 Pet., 2 and 3 John, Jude, and the Apocalypse, which were not found in the old Syriac Bible, were later supplied from the versions of Philoxenus (508) and Thomas of Heraclea (616). In addition to the canonical books, Ecclesiasticus (q.v.) was also translated from the Hebrew and the other deuterocanonical books (q.v.) probably from the Greek, while 4 Maccabees and a part of Josephus' Jewish War called 5 Maccabees, as well as several other apocryphal books, including the apocalypses of Baruch and Ezra (qq.v.), were also translated from the Greek. Translations of the Psalms of Solomon (q.v.) and the Odes of Solomon (q.v.) were discovered in 1909. A translation of the Greek text adopted by Origen called the Syro-Hexaplaric version was made by Paul of Tella in 617; and a revision of the New Testament was made by Jacob of Edessa (q.v.) at the end of the seventh century.

As early as any of the New Testament translations are the works of Bardesanes, the Gnostic (q.v.), who died in 222 and was a poet, philosopher, astronomer, and historian. His *Dialogue on Destiny* is extant; his 150 hymns are lost. A number of Gnostic hymns have, however, been preserved in the *Acts of Thomas*, written in the third century, among the Hymns of the Soul. In the fourth century Aphraates (q.v.) wrote his homilies, and the famous Ephraem (died 373) his commentaries on the Bible and on Tatian's *Diatessaron*, his exegetical discourses, and his hymns. Among the disciples of Ephraem were such writers as Aba, Zenobius, Balai, and Cyrillona. The most flourishing period of Syriac literature extended from c.400 to the Arabic conquest. In the course of the fifth century the great schism occurred which divided the Mesopotamian church between Nestorians and Monophysites (qq.v.) and severed both from the Catholic church. An eminent poet of this century was Isaac of Antioch (q.v.); and Narses of Maalsetha also deserves to be mentioned. Much of the early Nestorian literature is lost; but some works of Hamana (died 607), Babai (died 610), and Elias of Merv remain. Among the Monophysites, Aksenaya, or Philoxenus of Mabug, Jacob of Serug (died 521), Jacob Baradaeus, after whom the party was called Jacobites, and Jacob of Edessa (died 708) were perhaps the most influential writers. In addition to the strictly theological works, there grew up an historical literature, including the *Chronicle of Edessa*, the very excellent chronicle of Dionysius of Tell Mahre, many histories dealing exclusively with the Church, such as that of John of Ephesus (sixth century), and the translation and expansion of a work by Zacharias of Metylene, martyrologies and legends such as those of King Abgar and the Apostle Addai. Not only theological works, such as the *Clementine Recognitions*, the Apology of Aristides, the ecclesiastical history of Eusebius, and the commentaries of Theodore of Mopsuestia, were translated from the Greek, but also secular works like those of Homer, Æsop, Aristotle, Galen, and Hippocrates. Mana, Moses, Probus, Sergius, and Jacob of Edessa were especially active as translators, and Severus Sebokht of Nisibis wrote on astronomy and geography. After the Moslem conquest the Arabic language gradually gained on the vernacular. But Syriac still continued to be spoken in many localities and to be cultivated as a learned language. The use of two languages led to philological studies,

and many works on grammar and lexicography were written. Among these may be mentioned the grammar of Elias of Tírhan and the lexicons composed by Bar Ali Honain (died 873) and Bar Bahlul (963). Many books were translated from the Arabic in the tenth century, such as the *Kalilah wa Dimnah*, *Sindbad*, and Pseudo-Callisthenes' life of Alexander. Classical Syriac was written with great elegance by the Sabian Thabit ben Korrah (died 901) and his sons. (See SABIAN.) With the decline of the caliphate, the Syriac gained a more vigorous life, and numerous theological writers used it. Theodor bar Choni (tenth century) wrote with great freedom from prejudice on other religions than Christianity. Dionysius bar Salibi (twelfth century) is of interest for the history of the Crusades; and Michael of Melitene wrote a history of the world. The most important of these later writers are Abulfaraj Gregory, called Bar Ebhraya or Bar-Hebraeus (1226-86), who wrote a grammar, a commentary on the Bible, a history of the world, a commentary on Galen, translations from the Greek, essays on ethics and religion, astronomy, and other physical sciences (see BAR-HEBRAEUS); and Abhidisho (died 1318), a learned Nestorian who wrote the history of Syriac literature and other works. After the fourteenth century there were no noted writers.

The system of writing used by the Edessene Christians before the fifth century was a modification of the Aramaic script then in use in Syria, resembling most the Palmyrene. From the tenth century this writing was known as Estrangelo, or the writing of the gospel. The Nestorians continued to use it, while the Jacobites adopted for distinction a cursive form. At first vowels were not indicated at all. Subsequently vowel letters were used. But in the seventh century the Nestorians began to employ vowel points, and about 700 the Jacobites adopted some of the Greek vowels, which they wrote above or below the consonants to show the proper pronunciation.

The modern Syriac spoken with dialectical differences by the Nestorians in the West, those of Lake Urumiah, in the Kurdish mountains, and on the plain of Mosul, and by the Jacobites of Tur Abdin, exhibits, in addition to numerous Turkish, Kurdish, and Arabic loan words, certain peculiarities rendering it probable that it is a descendant of the Aramaic, once spoken in Assyria, rather than of the classical Edessene. In the dialect of Urumiah a considerable literature has been developed by American missionaries.

**SYRIAC VERSIONS.** See BIBLE.

**SYRIAN PROTESTANT COLLEGE.** An institution of learning at Beirut, Syria, founded in 1863 and incorporated under the laws of New York in 1864 by the Trustees of the Syrian Protestant College. The college was opened in 1866; in 1867 the school of medicine was organized; in 1900 a school of commerce was opened; in 1905 a nurses' training school; in 1909 the teachers' training course; and in 1910 the school of dentistry was added. There were in 1916 eight departments including in addition to the above the preparatory department, the school of pharmacy, and the school of biblical archaeology and philology. The college occupies a site of 40 acres overlooking the Mediterranean and comprises 26 buildings. English is the language of instruction, having begun to replace Arabic in 1880. In 1913-14 the institution had an enrollment of 961 students, of whom 545 were in departments above the preparatory. There is a graduate body since the foundation of the college of 2306 members. The total faculty includes about 70 members. The president is Rev. Howard S. Bliss.

**SYRIAN RITE.** See LITURGY.

**SYRIN'GA** (Neo-Lat., from Gk. *σῦριγξ*, *syrix*, pipe, tube; name first given to the mock-orange because its stems, after removal of the pith, were used as pipes). A genus of plants of the family Oleaceae. The English common name is lilac (q.v.). *Syringa* is also a name very commonly applied to the mock orange, or *Philadelphus* (q.v.).

**SYRIN'GOMYELIA** (Neo-Lat., from Gk. *σῦριγξ*, *syrix*, a pipe + *μυελός*, *myelos*, marrow). A disease of the spinal cord characterized by the formation of cavities and the growth of new tissue resembling glioma in its central parts. Its cause is not accurately known, though it may depend upon anomalous embryonic development, and it apparently follows infectious diseases as well as wounds upon the hands. It is not caused by alcohol or syphilis, nor is it hereditary. It often appears in women after childbirth. The disease is comparatively rare and appears between the eleventh and the thirtieth year; it is more frequent in males than in females, in the proportion of 2.2 to 1. The symptoms are pains in neck and arms with reduced sensation in the hands, atrophy of muscles in hands, arms, and shoulders, with twitchings, followed by wasting in muscles of back, thighs, and legs. The hands become clawed, the feet deformed, and the spine is curved, in extreme cases. Loss of sensation to temperature and pain, while not to touch, occurs, and is considered pathognomonic. Eruptions and ulcerations appear on hands and face, and other changes occur. The disease lasts from five to 20 years, and the prognosis for checking it is not good. It is incurable. Rest and general tonic treatment, hydrotherapy, and massage, as well as silver and arsenic, are measures tried. Consult Church and Peterson, *Nervous and Mental Diseases* (Philadelphia, 1914).

**SYRINGOPORA** (Neo-Lat. nom. pl., from Gk. *σύριξ*, *syrix*, pipe, tube + *πόρος*, *poros*, passage, pore). A genus of fossil tabulate corals in which the coral mass consists of a bundle of slender cylindrical tubes that rise from a common base and that are connected at intervals by slender hollow horizontal processes or plates. The genus ranges through the Upper Silurian, Devonian, and Lower Carboniferous formations.

**SYRINX** (Neo-Lat., from Gk. *σύριξ*, pipe, tube). A simple instrument of reeds, probably the most ancient of musical instruments. It is thought identical with the Hebrew Ugab, mentioned in the Bible. The Greeks supposed it to have been made by the god Pan out of reeds, and hence its secondary name Pandean pipes. It was formed of seven, eight, or nine short hollow reeds cut in graduated lengths, so as to produce a musical scale, and then fixed together by wax. The lower ends were closed and the upper ones open and on a level, so that the lips could easily pass over the pipes.

**SYRINX**. An organ peculiar to birds, concerned in the production of voice. It is usually composed of several modified rings of the lower trachea or upper bronchial tubes, the inner half of which are covered by a thin medial fold of membranous tissue. Special muscles control the tension of this membrane, and by thus varying the size of the aperture through which the air leaves the lungs, varying tones are made and controlled. See **BIRD**, and consult the bibliography there given.

**SYRLIN**, zër'lén, JÖRG, the Elder (c.1425-91). A famous German wood carver and sculptor, active at Ulm from about 1458, one of the most remarkable masters of his time. The three-seated stool of 1468 at the entrance of the choir in the cathedral, and his chief production, the stately double row of choir stalls (1469-74) there, the first of their kind in richness of detail and skillful workmanship, exhibit a plastic beauty and freedom of form unequalled by any contemporary effort. His earliest known work is a singing desk (1458) in the Ulm Museum, and as an isolated production in stone is to be mentioned the fountain in the market square, known as the "Fischkasten" (1482).

His son and pupil, JÖRG the Younger, carried on his father's workshop, but he lacked the unity and repose of the elder Syrlin. He carved the choir stalls (1493) and the celebrants' stool (1496), in the church at Blaubeuren, also a three-seated stool (1505) in the Neithardt Chapel of Ulm Cathedral, and in the latter the sounding board of the pulpit (1510). Consult the monograph by Grill (Strassburg, 1910), and Baum, *Die Ulmer Plastik* (Stuttgart, 1911).

**SY'RO-CHALDÆ'ANS**, or **SY'RO-O'RIEN'TALS**. See **CHALDÆAN RITE**.

**SYRKOM'LA**, WLADYSŁAW. Pseudonym of LUDWIK KONDRATOWICZ (q.v.).

**SYRPHUS** (sēr'fūs) **FLY** (Neo-Lat., from Gk. *σύρφος*, *syrfhos*, *σέρφος*, *serphos*, gnat). A fly of the family Syrphidae, many species of which are of much economic importance. More than 300 species occur in the United States. They are stout-bodied flies and vary greatly in color. Many species closely resemble bees and wasps. Nearly all of them are flower flies and pollen carriers. Many syrphus flies in the larval state feed upon plant lice and other soft-bodied insects. Others live in decaying wood or in manure or soft mud, in the sap of trees

or in the stems of plants, or in fungi, or as guests of ants and bumblebees. The rat-tailed maggot (q.v.) is an example of the forms found in soft mud or in manure. Those which live in ants' nests belong to the genus *Microdon* and are among the strangest insect larvae known. Those which live in the nests of bumblebees belong to the genus *Volucella*, and the adult flies resemble bumblebees.

**SYR'TIS MA'JOR** and **SYR'TIS MI'NOR**. The ancient names of two gulfs on the north coast of Africa. See **SIDRA** and **GABES**.

**SYRUP**. See **SUGAR**, **MANUFACTURE OF**.

**SYSTOLE**, sis'tō-lē. See **HEART**.

**SYS'TYLE**. An arrangement of classic columns in which the intercolumniation is equal to only twice the diameter of the column. See **COLUMN**; **INTERCOLUMNIATION**.

**SYZ'RAN**, siz-rän'y'. A river port in the Government of Simbrisk, Russia, on the River Syzran, near the right bank of the Volga (Map: Russia, G 4). It lies in a low district, submerged during the annual rise of the Volga. The town is known as a grain exporting centre. Pop., 1911, 46,234.

**SZABADKA**, sō'bōt-kō. See **THERESIOPEL**.

**SZARVAS**, sōr'vōsh. A town of Hungary, in the County of Békés, 85 miles southeast of Budapest, on the left bank of the Körös (Map: Hungary, G 3). Pop., 1900, 25,773; 1910, 28,543.

**SZÁSZ**, sās, KÁROLY (1829-1905). An Hungarian poet and translator, born in Nagy-Ényed, Transylvania. During the revolution of 1848-49 he fought in the Honvéd army, then studied theology, and was engaged in teaching and pastoral work until 1865, when he was appointed counselor in the Ministry of Public Worship. Two years later he was appointed inspector of schools, and in 1876 again ministerial counselor. In 1884 he became reformed bishop at Budapest. He was elected to the Hungarian Academy in 1858. Besides numerous lyrics he wrote the epic poems *Almos* and *Salomon*, several dramas (*Zrínyi*, *Emperor Joseph*, *Herod*, *Friar George*), and the tragedy *The Death of Attila* (1888), but his reputation rests mainly on his masterly translations of the poets, Dante (*Divina Commedia*), Shakespeare, Moore, Tennyson, and Molière. He is also noted for the translations embodied in *A világirodalom nagy eposzai* (The Great Epics of the World's Literature, 2 vols., 1882).

**SZATMÁR-NÉMETI**, sōt'mār-nā'mē-tē. A town in the County of Szatmár, Hungary, 63 miles northeast of Debreczin, on the right bank of the Szamos (Map: Hungary, H 3). It contains a beautiful cathedral. Szatmár-Németi was founded by the Germans in the eleventh century. Pop., 1900, 26,881; 1910, 34,892, chiefly Magyars.

**SZÉCHÉNYI**, sá'chēn-yē, ISTVÁN (STEPHEN), COUNT (1792-1860). An Hungarian statesman, born in Vienna. As a youth he served in the Austrian army in the wars with Napoleon, and afterward traveled. In 1825 he took his seat in the Upper House of the Hungarian Parliament. As a leader of the National party he endowed the Hungarian Academy of Science, a conservatory of music, and a theatre. To his exertions were due the erection of the great suspension bridge between Pest and Buda, the improvement of navigation at the Iron Gate, the regulation of the Theiss, and the in-

trodition of steamboats on the Danube. In 1847-48 he opposed the extreme measures of Kossuth, but later fell in with the popular movement and became a member of the ministry under Batthyányi and Kossuth in 1848. Becoming insane soon after, he was taken to the asylum at Döbling, near Vienna, where, though he partly recovered, he spent his remaining years. In March, 1860, his papers were searched by the police, and in a fit of excitement he shot himself. Consult Lónyay, *Graf Stephan Széchenyi und seine hinterlassenen Schriften* (Pest, 1875).

His son BÉLA became known for wide travels and explorations in the East Indies, Japan, China, Java, Borneo, western Mongolia, and the frontiers of Tibet. In 1893 he published in German an account of his experiences.

**SZE-CHUEN**, or **SZE-CHUAN**, sě'chwän' (Chin., Four Rivers). The largest of the eighteen provinces of China (Map: China, H 6). Area, 218,480 square miles. The western part of Sze-chuen is a wild inhospitable region of high mountain ranges, with limited agricultural resources, and rivers too impetuous for junk navigation, inhabited chiefly by non-Chinese tribes—Man-tse, Si-fan, and Losos (q.v.). The eastern portion east of the Min River including the plain of Cheng-tu, 2000 square miles in area and 1800 feet above sea level, is a rich fertile country of innumerable small valleys. The province is well watered by the Yang-tse and its numerous tributaries—the Yalung, the Min, the T'o, and the Kia-ling from the north, and the Ta-kwan, the Nan-kwang, the Yung-ning, the Chih-shui, the K'i-kiang, and the Kung-t'an from the south. Nearly all of these are obstructed in parts by rapids, but they nevertheless form most valuable avenues of communication in an otherwise difficult country. The climate is not extreme, although it is continental in character and changes are sudden. The rainy season begins in May and is at its height in July.

Sze-chuen is rich in minerals, especially in coal and iron. Coal is widely distributed, but the seams are thin and the quality does not compare with the coal of Kansu, Shansi, Honan, or even Hunan. Copper, silver, gold, and lead occur in small quantities. Notwithstanding the mountainous character of the country, agriculture has been brought to a high state of perfection; the province produces everything needed for home consumption except cotton and wool. The hillsides in many places have been terraced. Wheat is a winter crop. Rice, the staple article of diet, is extensively grown. Other crops are barley, maize, millet, buckwheat, pulse, potatoes, tobacco of fine quality, tea, sugar, indigo, and sesamum, rape, and other oil-producing plants. Hemp is the only textile plant grown, except that used in the manufacture of grass cloth.

Other important products are silk, white wax, vegetable fallow, tungoil, rhubarb, medicines, musk, and hides. Wool is imported from Shensi, Tibet, Koko Nor, and other regions. Cotton, both raw and manufactured, comes chiefly from Hupeh. Cotton spinning and weaving are important home industries, and the cloth is exported to Tibet and Yunnan, along with tea and silk. Iron manufacture from the ores of the province is an important industry. Enormous quantities of salt are obtained from brine springs from 500 to 2000 or more feet in depth, the brine being evaporated by natural gas or

coal. It is a government monopoly, and brings in a large revenue. Many people are also employed in paper making and the production of fans, umbrellas, crape, gauze, silk embroideries, etc.

Sze-chuen can be entered from the east by only two important routes: either overland through Shansi and Shensi, along difficult mountain paths infested by robbers, or up the Yang-tse by steam to Ichang (q.v.), and thence by native, specially constructed junks, hauled slowly and at great risk up rapids and through deep gorges. Within the province itself there are many pack roads. Capital, Cheng-tu (q.v.), where resides the Governor-General, who also has charge of East Tibet (q.v.). The principal port opened to foreign trade is Chungking (q.v.). The population is estimated at about 54,500,000. Consult Baber, *Travels and Researches in Western China* (London, 1882); Hosie, *Three Years in Western China* (New York, 1890); and Bishop, *The Yang-tse Valley and Beyond* (ib., 1901).

**SZEGEDIN**, sēg'ed-ĕn (Hung. *Szeged*). A royal free city of Hungary, next in size to Budapest, in the County of Csongrád, on the right bank of the Theiss a little below the confluence of the Maros, 118 miles by rail southeast of Budapest (Map: Hungary, F 3). The town has been largely and handsomely rebuilt since the terrible inundation of 1879, when 2000 persons lost their lives. A high dike has been constructed to protect the city from another such disaster. The modern streets are wide and there are several attractive squares. Szegedin has a fine rococo town hall, a Gothic cathedral, a handsome theatre, and other stately edifices. The Franciscan monastery contains an excellent library (89,000 volumes) and a museum of antiquities. There are also a Minorite and a Piarist monastery. The principal manufactures are paper, salt, cloth, the famous Szegedin soap, and the red pepper usually called paprika. As the commercial centre of the great Hungarian Alföld it has a brisk trade in grain, wool, tobacco, lumber, etc., both by rail and river, the Theiss being lined with quays. Boat building is extensively carried on. New Szegedin lies on the opposite bank. Szegedin was fortified by the Turks, who held it from 1526 for 160 years. Pop., 1900, 102,991; 1910, 118,328, mostly Roman Catholic Magyars.

**SZÉKELY**, sǎ'kě-lě. See DOZSA.

**SZEKLERS**, sēk'lērz. See TRANSYLVANIA.

**SZÉLL**, sǎl, KOLOMAN DE (1843-1915). An Hungarian statesman, born in Rátót, and educated at Budapest and Vienna. Entering local politics in 1867 and Parliament the next year, he so distinguished himself by his financial interpellations that in 1875 he was offered the portfolio of finance by Wenckheim. He retained it until 1878, when he retired because of his disapproval of the Bosnian occupation, but kept his seat in Parliament. He then became president of the Hungarian Bank in Budapest, refusing every inducement to reënter the cabinet until the fall of Bánffy in 1899, when he rose to the head of the government as Minister of the Interior and President of the Council. He retired in June, 1903.

**SZE-MA KWANG**, sǔ'má kwāng', or **SSŪ-MA KUANG** (1019-86). A distinguished Chinese statesman and historian, born in Hsia, a district of Honan. At 19 he entered the public

service, rose rapidly, became president of the Hanlin-Yüan (q.v.) and a Minister of State. He is specially noted for the persistency and the vigor of his opposition to Wang An-shih (q.v.), "the innovator." Failing to induce the Emperor to dismiss Wang and repeal his reform, Sze-ma retired to private life, and devoted himself to literature and especially to the preparation of his *History of China* (403 B.C. to 960 A.D.), in 294 books, called the *Comprehensive Mirror for the Aid of those who Govern*. In 1085, on the death of the Emperor, he was taken into favor by the Empress Regent, was reinstated in office, and at once set about the repeal of the reforms of Wang, but he died in the following year. Besides the *Comprehensive Mirror* he was the author of the *Ki-ku-lu* (Investigations into Antiquity), in 20 books, which extends to 1067 A.D., an etymological dictionary, and many miscellaneous essays. Consult Rémusat, *Nouveaux mélanges asiatiques* (2 vols., Paris, 1829), and H. A. Giles, *History of Chinese Literature* (New York, 1901).

**SZEMAO**, sū'mou'. A town in the southwestern part of the Province of Yunnan, China, situated 185 miles southwest by west of Yunnan-fu. The trade of Szemao is almost entirely with Burma and Tibet. The town was opened to foreign residence and trade in 1897. Pop., 9000.

**SZE-MA TS'EN**, sū'má tsyēn', or **SZŪ-MA CH'EN** (c.145-c.85 B.C.). The first great historian of China. He was born in Lungmun, in Honan, made good progress in learning while still a child, and at 20 began a great tour of the Empire. On his return he entered the public service, and was commissioned to inspect and report upon the regions now known as Sze-chuen and Yunnan, then recently conquered. On the death of his father in 110 B.C. he succeeded him as historiographer, and entered upon the task of completing the great historical work which had been begun by his father. This he accomplished 91 B.C., but the work did not appear until some years after his death. It is entitled *Shih Ki* (Historical Records), and in 130 books gives the history of the country from 2697 B.C. to 104 B.C. For specimens of his style, consult H. A. Giles, *History of Chinese Literature* (New York, 1901), and Friedrich Hirth, *Ancient History of China* (ib., 1911).

**SZENTES**, sēn'tēsh. A market town of the County of Csongrád, Hungary, on a tributary of the Theiss, 28 miles north by east of Szegedin (Map: Hungary, G 3). The town formerly suffered from inundations, but is now protected by a number of large dikes. Agriculture and fishing are the principal pursuits, and wine is exported. Pop., 1900, 31,308; 1910, 31,593, mostly Lutheran Magyars.

**SZEW CZENKO**, TARAS (1814-61). See SHEVTCHEENKO, TARAS GRIGORYEVITCH.

**SZIGLIGETI**, sē'glē-gā'tē, EDUARD (1814-78). An Hungarian dramatist, whose real name was Joseph Szathmáry. Born at Grosswardein, he studied engineering, but in 1834 went on the stage at Buda and in 1837 became secretary and stage manager of the newly erected National Theatre at Pest. Of his numerous dramas sev-

eral were crowned with prizes by the Hungarian Academy, among them *Róza*, *Vándor színészek* (Itinerant Actors), *Pál Béli*, *Laczi Imre*, and *Béla IV*, but the greatest success attended his popular plays drawn from national life, many of which found their way also to the German stage, notably *The Deserter*, *Two Pistols*, *The Csikós*, *The Foundling*, and others. Besides his excellent *A dráma és válfajai* (The Drama and its Species, 1874), he published biographies of Hungarian actors (1878). He was elected a member of the Hungarian Academy (1840) and of the Kisfaludy Society (1845), and in 1873 director of the National Theatre. Consult Pál Gyulai, *Memorial Addresses* (Budapest, 1879 and 1890), and P. Rakoczay, *Eduard Sziglietti's Life and Works* (Pressburg, 1901). Both of these works are written in Hungarian.

**SZILÁGYI**, sē'lād-yē, SÁNDOR (1827-90). An Hungarian historian, born at Klausenburg, and educated there and at Maros-Vásárhely. From 1853 to 1867 he was connected with the reformed college of Nagy-Kőrös, after which he was appointed secretary in the Ministry of Public Instruction, and in 1879 became librarian of the university at Budapest. He founded the Hungarian Historical Society, of which he was secretary until his death, and of whose organ, *Századok* (The Centuries), he was editor. He was the moving spirit in the revival of historical interest which took place in Hungary after 1849. Among his works are the *Monumenta Comitatus Regni Transylvaniae* (21 vols., 1875-98), a collection of papers from Hungarian-Turkish sources in nine volumes, and a national history, 10 vols. (1894-98). His best-known monographs are: *Gabr. Báthory* (1867); *Siegmund Rákóczi* (1886); *Georg Rákóczi II* (1891); *Georg Rákóczi I* (1893). Consult Arpád Károlyi, *Memorial Address* (Budapest, 1900).

**SZOLNOK**, sōl'nók. A town of Hungary, the capital of the County of Jazygia—Great Cumania—Szolnok, 57 miles southeast of Budapest, on the right bank of the Theiss, at the mouth of the Zagyva (Map: Hungary, G 3). On March 5, 1849, the Austrian General Karger was defeated here by the Hungarians. Pop., 1900, 25,379; 1910, 28,930, mostly Roman Catholic Magyars.

**SZUJSKI**, shwīs'ki, JÓZEF (1835-83). A Polish historian and Romantic dramatist, born at Tarnov, Galicia. He founded with Tarnowski the *Przegląd Polski* in 1867, was appointed professor of Polish history at the University of Cracow in 1869, and later also secretary general of the Cracow Academy. In 1881 he was called to a seat in the Austrian House of Lords. He published many mediæval documents and chronicles bearing upon Polish history and in his *Dzieje Polski* (1862-66; new ed., 1896) presented a history of Poland in the manner of Guizot. In German he wrote *Die Polen und Ruthenen in Galizien* (1882). Besides poems and tales he produced a number of historical dramas, such as *Halszka z Ostroga* (1858), *Jęczy Lubomirski* (1863), *Maryna Mniszechovna* (1876), *Jadwiga*, *Kopernikus*, *Wallace*, and others.

# T

---

**T** The twentieth letter of the English alphabet. Its Semitic original, *tau*, the last letter of the Phœnician alphabet, meant "cross" and was so called on account of the early shape of the character. See ALPHABET, especially Plate containing characters.

As a phonetic character *t* is the voiceless alveolar explosive. To form this sound the tongue tip is brought into contact with the gums of the upper front teeth and the breath is made to escape explosively. Its corresponding voiced explosive is *d*. These two sounds are most frequently called dentals, or teeth sounds, though the teeth have in reality no part in their production. Other terms are lingual, front lingual, tongue tip, etc.

English *t* represents in general an original Indo-Germanic *d*, as Skt. *dam*, to tame, Gk. *δαμάω*, Lat. *domare*, Eng. *tame*. It may also represent an original Indo-Germanic *t*, as in Skt. *stigh*, to step, Gk. *στρίχω*, AS. *stigan*, Eng. *stile*. An excrecent *t* occurs especially between *s* and *r*, as a glide sound between the median and lateral positions of the tongue, as in Eng. *stream*, compared with Skt. *sravas*. An inorganic *t* has also been developed in some modern English words after a final *s*, as *amidst* from *amiddes*, amongst from *amonges*, and *whilst* from *whiles*. As in French, *t* shows a tendency to become palatalized before palatal vowels, and in a great number of words, like *nation*, *partial*, *faction*, etc., it has an *sh* sound.

The digraph *th* represents both the voiced and the voiceless spirant, as *then*, *thin*. It may be pronounced *t*, as *Thames*, *thyme*, as may also the *-ed* of the preterite and perfect participle, as *dressed*. In many words *t* is silent, as in *châsten*, *moisten*, *christen*, *castle*, *gristle*, *hustle*.

As a mediæval numeral T = 160; T̄ = 160,000. In music *t* = tenor, tempo. Consult: Philippe Berger, *Histoire de l'écriture dans l'antiquité* (Paris, 1892); Maurice Prou, *Manuel de paléographie latine et française* (ib., 1910); Sir E. M. Thompson, *Introduction to Greek and Latin Palæography* (London, 1912); Passy, *Petite phonétique comparée des principales langues européennes* (2d ed., Leipzig, 1912); Van Hoesen, *Roman Cursive Writing* (Princeton, N. J., 1915). See DENTALS; LETTERS; PALEOGRAPHY; PHONETICS.

**TAA**. See PAGODA.

**TAAFFE**, tã'fe, EDUARD, COUNT (1833-95). An Austrian statesman of Irish extraction, born at Prague. He entered the public service

in 1857 and was appointed Governor of Salzburg in 1863. He was Minister of the Interior in 1867 and Minister of National Defense in 1868, becoming President of the Council after Prince Auersperg's retirement in September, 1868. He resigned in January, 1870, but three months later became again Minister of the Interior and remained in office until February, 1871, when he was made Governor of Tirol and Vorarlberg. In February, 1879, Taaffe was again appointed Minister of the Interior, and in August he formed a new cabinet, over which he presided until 1893. The distinguishing feature of his administration was the greater weight given to the Czechs and the Poles as well as to the clericals in public affairs and his vain effort to conciliate the divergent nationalities of the Empire. A radical electoral reform measure, which displeased all parties, compelled him to retire in November, 1893.

**TAAL**, tãl. A town of Luzon, Philippines, in the Province of Batangas. It is on the Transpit River near the Gulf of Balayán and is connected by a bridge with Lemerí on the opposite bank. It is the principal seaport of the province, with a large trade in coffee, sugar, and cotton goods in addition to the local industries of agriculture, fishing, and stock raising. The old town of Taal was situated on the bank of the lake of the same name near the volcano Taal and was destroyed in 1754, while it suffered severely in the eruption of Jan. 30, 1911. Pop., 1903, 17,525, a considerable number of whom are of Chinese origin.

**TAAL**, or BOMBÓN. A volcano in central Luzon, Philippines (Map: Philippine Islands, C 3). It forms a small island in the middle of Lake Taal, which lies 10 miles southwest of the Bay Lagoon. Its height is only 1050 feet, but it has a crater of 7650 feet in diameter. A number of eruptions have been recorded since the discovery of the islands, the most destructive occurring in 1873 and Jan. 30, 1911.

**TABAGO**, tà-bã'gõ. An island of the West Indies. See TONAGO.

**TABAN'IDÆ** (Neo-Lat. nom. pl., from Lat. *tabanus*, gadfly). A numerous family of dipterous insects which live by sucking the blood of horses, cattle, and other animals and are popularly known as gadflies, horse flies, or deer flies. See GADFLY.

**TAB'ARD**, THE. A famous inn of old London. It was on High Street, Southwark, near Kent Road, and must have been in existence as early as the fourteenth century, for Chaucer starts his pilgrims from it on their journey to

the shrine of Thomas à Becket. Its sign was a tabard (sleeveless jacket). At the end of the sixteenth century it was in high repute. In the seventeenth century it was damaged by the Great Fire, and in the process of restoration the sign was changed to a Talbot. Its site is now occupied by the freight depot of the Midland Railway.

**TABARI**, tā-bā'rê (Ar. *Abū Ja 'far Muḥammad ibn Jarīr al-Tabarī*) (838-923). Author of the first universal history in Arabic. A Persian, born in Tabaristan, he studied at Bagdad and in Syria and Egypt. His great historical work is the *Annals*, a history of the world from the creation to 302 A.H. (914 A.D.). This was edited by De Goeje (15 vols., Leyden, 1879-1901). Nöldeke's *Geschichte der Perser und Araber zur Zeit der Sassaniden* (Leyden, 1879) is a translation of portions of the *Annals*. Tabari's extensive commentary on the Koran stands superior to all other commentaries (ed. by Kern, 31 vols., Cairo, 1902-03). Consult Brockelmann, *Geschichte der arabischen Litteratur* (2 vols., Weimar, 1898-1902), and Haussleiter, *Register zum Qoran-Kommentar des Tabari* (Strassburg, 1912).

**TABASCO**, tā-büs'kō. A maritime state of Mexico (Map: Mexico, M 8). Area 10,372 square miles. Tabasco has no railways nor good roads; its principal rivers, the Usumacinta and the Grijalva, with their tributaries furnish means of transportation. The climate is hot and unhealthful and the rainfall very abundant. Agriculture is the leading industry, and the fertile soil produces sugar, cacao, rice, rubber, coffee, corn, and fruits. Stock raising is of secondary importance. Pop., 1910, 187,574. Capital, San Juan Bautista.

**TABASHEER**, or **TABASHIR**, tāb'a-shēr' (Hind. *tabāshīr*, Skt. *tavaksīra*, *tvaksīra*, bamboo manna). A substance sometimes found in the cavities or tubular parts of the stems of bamboos. Its formation is believed to be due to disease or injury to the plant. The substance, which has been found to be almost pure silica, is white, opaque, or translucent, and breaks into irregular pieces resembling dry starch. It was formerly in high repute among the Hindus as a tonic. Tabasheer is remarkable as having the lowest refracting power of any known substance.

**TABB**, JOHN BANISTER (1848-1909). An American poet, born in Virginia. He was a Roman Catholic priest and instructor in English literature at St. Charles College, Ellicott City, Md. The verse of Father Tabb, small in amount but often of good quality, comprises: *Poems* (1883); *An Octave to Mary* (1893); *Lyrics* (1897); *Poems Grave and Gay* (1899); *Two Lyrics* (1900); *Quips and Quiddits* (1907); *Later Poems* (1910).

**TABERNACLE**, tāb'ēr-nā-k'l (Lat. *tabernaculum*, dim. of *taberna*, hut, booth; connected with *tabula*, plank, board). Primarily a tent, booth, or shelter, and hence also (1) a shrine or portable receptacle, (2) a fixed receptacle for a statue, (3) a portable tent or sanctuary, (4) a large building for worship or religious gatherings. In Roman Catholic ecclesiology the term is applied to the shrine or receptacle in which the consecrated elements of the Eucharist are kept; usually a richly adorned shrine above the altar, often of marble or metal, inclosing a wooden receptacle. A red lamp is kept always lighted before it. In architecture the tabernacle is a tall narrow niche for a statue, with

a richly adorned projecting canopy above it and a carved corbel at its foot, on which the statue stands. It is a common feature on Gothic exteriors. In sense (4) a tabernacle is a large hall for religious worship or for revival gatherings, of either permanent or temporary construction. In this sense it is used especially by the nonliturgical denominations.

In biblical usage the tabernacle denotes the portable sanctuary which, according to the traditional view, was carried about by the Israelites in the wilderness. The command to build this structure is found in Ex. xxv. 10-xxvii. 19, and the account of its construction (in almost identical terms) in Ex. xxxvi. 8-xxxviii. 31. While it is called a tent, it was in reality a house, having upright walls of thick boards on three sides and a curtain on the fourth. The wooden framework had four coverings—one of linen, one of black goats' hair, one of rams' skins dyed red, and one of the skins of wethers. In front the curtain was fastened to pillars of acacia wood, with copper bases and capitals covered with gold. This structure was divided into two parts, separated by an inner curtain, supported by four pillars with bases of silver and wholly overlaid with gold. The outer and larger apartment was the Holy Place, accessible to priests only; the inner, the Holy of Holies, was entered only once a year by the high priest. Around the sanctuary was a court inclosed by curtains supported by 60 pillars of wood with bases of bronze and capitals overlaid with silver. In the Holy of Holies stood the Ark of the Covenant; in the Holy Place the table of shewbread, the golden candlestick, and the altar of incense; in the court stood the brazen altar of burnt offering and around it were ash pans, shovels, bowls, forks, and firepans of brass, while in the middle was the great brazen laver. The tabernacle is described as being of extraordinary splendor and of costliest materials. It stood in the centre of the camp and was carried by a large retinue of men when the camp moved. Many modern scholars regard the description as wholly imaginary and devoid of historical value. It is considered by them as having been drawn on the basis of Solomon's temple and projected into the Mosaic period. This, they maintain, is indicated not only by the impossibility of such a house being constructed and carried about in the wilderness, but also by the fact that the earlier records know nothing of a tabernacle of this kind, while some passages seem to have preserved the picture of a much simpler tent where Yahwe revealed Himself to Moses (Ex. xxxiii. 7 et seq.; Num. xi. 25, xii. 5, xiv. 10). This "tent of meeting" (*'ōhel mō'ed*) stood outside the camp and was only a small tent with a single custodian, and Yahwe revealed Himself there in a cloud at the door. It is not impossible that the memory of such a portable shrine, common to many nations, carried about while they were still nomads, survived among some of the tribes that afterward formed the people of Israel. When David brought the ark to Jerusalem, he made a new tent for it (2 Sam. vi. 17) and placed it at Gihon, the modern Ain Sitti Maryam (1 Kings i. 38). Within the tent there were a horn of oil for the anointing of kings (1 Kings i. 39) and an altar with horns (ib. i. 51; ii. 28). David's plan to build a house was frustrated by Nathan on the ground that Yahwe had never dwelt in a house, but

always lived in a tent as He walked about (2 Sam. vii. 6). It is possible that the destruction of Shiloh was looked upon in some circles as the punishment for causing Yahwe to dwell in a house. Sellin and Gressmann think that, while the story of the tabernacle has obviously been embellished, there is a nucleus of historic fact in it, and that the tent of the nomadic period may already have contained Urim and Thummim, ephod, teraphim, the magic staff of Moses, the brazen serpent, the blossoming staff of Aaron, the jug with manna, and possibly also an altar. Popper has shown that the account of the construction, repeating almost verbatim the command, is a very late expansion of the text.

**TABERNACLES, FEAST OF** (Heb. *Ḥag hašukkkōth*). The name given in the Old Testament to a festival which marked the close of the harvest of fruit, oil, and wine in Palestine. As a harvest festival it is also known as the Feast of Ingathering (Ex. xxiii. 16; xxxiv. 22) and can be traced back to the Canaanites. The festival was marked by general jubilation and by a visit to some sanctuary, accompanied by sacrifices for the purpose of testifying gratitude to the giver of fertility. Among the popular customs observed by the Canaanites was the erection of booths in the vineyards, in which the people dwelt during the vintage. Hence the name Festival of Booths (or Tabernacles) in the four passages besides those already mentioned in which the ritual is set forth (Deut. xvi. 13-15, xxxi. 10-13; Lev. xxiii. 34-36, 39-44; Num. xxix. 12-40). This Canaanitish agricultural festival was adopted by the Hebrews and was given an historical aspect by interpreting the custom of dwelling in booths as a reminiscence of the nomadic stage in the life of the people and more particularly of the traditional 40 years' sojourn in the wilderness when the tent formed the only habitation. It is possible that the compromise between a Canaanitish harvest festival and a nomadic festival was facilitated by the fact that *šukkkōth* may signify tents of hides or cloth as well as booths made of branches of trees. The pristine importance of the festival may be gathered from the fact that it was called "the festival" par excellence and that originally it was the single occasion in the year on which a pilgrimage to a sanctuary was prescribed. Hence, as Volz has pointed out, it was originally Yahwe's New Year's festival. As finally shaped in the Hebrew ritual, it extended over the seven days from the fifteenth to the twenty-second day of Tishri (the seventh month), and in addition the eighth day was observed as a "solemn assembly," which in Rabbinical Judaism developed into the festi-

val of Rejoicing of the Law. Booths were erected on the roofs of houses or in the courts and streets, made of olive, pine, myrtle, and palm branches. (Cf. Neh. viii. 15.) The sacrifices prescribed for this feast were more numerous than for any other, sin offerings (one kid daily) and burnt offerings (two rams and 14 lambs daily) being prescribed, besides 70 bullocks during the seven days (13 on the first day, 12 on the second, and so on in a diminishing scale). Besides these distinctly biblical enactments we find in the days of the second temple daily processions around the temple altar, the priestly procession to Siloam to fetch water and its libation in connection with the morning sacrifice (cf. John vii. 37), the singing of the Hallel psalms (Ps. cxiii-cxviii), the lighting of the four great golden candelabra in the Court of the Women (John viii. 12), and the carrying of palm branches entwined with myrtle and willow together with a specimen of the ethrog (or citron) fruit by the worshipers into the synagogues. The erection of booths and the waving of the palm branches with the ethrog are customs still observed in orthodox Jewish communities. Consult: I. Benzinger, *Hebräische Archäologie* (2d ed., Tübingen, 1907); P. Volz, *Das neujahrsfest Jahwes* (Leipzig, 1912); E. Sellin, "Das Zeit Jahwes," in *Alttestamentliche Studien Kittel dargebracht* (ib., 1913).

**TABES DORSALIS**, tā'bēz dōr-sā'lis. See LOCOMOTOR ATAXIA.

**TABES MESENTERICA**, mēs'en-tēr'ī-kā. See MESENTERY AND ITS DISEASES.

**TABLATURE** (Fr. *tablature*, from Lat. *tabula*, plank, table, tablet). A method of musical notation used in the fifteenth and sixteenth centuries. At first it was chiefly employed for the lutes and viols. The lines and spaces of the staff did not represent the pitch of the notes, but the frets of the instrument. Either the lines or the spaces were used, but not both. These lines or spaces varied according to the number of the strings of each instrument. The French and English tablatures denoted the tones by letters, the Italian by numerals. But the German or organ tablatures employed a regular staff and musical notation for the melody or highest part, while the tones completing the harmony were written by letters vertically below each note of the melody. All tablatures had three points in common: (1) all letters or figures belonging to the same chord were written vertically one above the other; (2) all employed lines for the division of the separate bars or measures; (3) all made use of a uniform system to denote the time value of notes and rests. These signs were written either above or below the numbers or letters. Rests were denoted by a horizontal line placed below the note sign.

**TABLELAND**. See PLATEAU.

**TABLE MOUNTAIN**, or **TAFELBERG**, tā'fel-bērg. A mountain of Cape of Good Hope Province overlooking Cape Town and Table Bay (Map: Cape of Good Hope, D 10). It is 3550 feet high and is named for its level top of a mile in length. It is often covered with a white cloud, which is called the Tablecloth.

**TABLES**. See FURNITURE.

**TABLES, FENCING THE**. See FENCING THE TABLES.

**TABLES, LUNAR**. Tabular lists of numerical data based on the elements (q.v.) of the moon's

orbit and used for calculating the moon's position on the sky. See NAUTICAL ALMANAC.

**TABLET OF ABYDOS.** See ABYDOS.

**TABLETS, WAX.** See PALEOGRAPHY, *Materials*.

**TABLEWARE, SILVERPLATED.** An imitation of solid silver plate (see PLATE) produced by using a silver of cheaper metal. The earliest form was Sheffield plate, named from the English city where the process now abandoned was developed. Birmingham also became an important centre of the industry. In 1742 Thomas Bolsover of Sheffield, while repairing a knife, accidentally overheated it, so that the silver melted and spread in a thin coating over the copper. The fact that this coating stuck fast when cooled impressed him, and thus was invented a method of coating small copper objects with silver by the application of heat. Later Joseph Hancock improved the process so that large objects could be produced. Starting with a bar of copper or copper alloy between thin bars of silver, he heated them to fusion and then rolled them and rerolled them into a large flat sheet of silver-plated copper that could easily be shaped into all kinds of tableware, which were still further embellished by soldering on handles, knobs, and other ornaments of cast or stamped silver. Of course, where a cut edge of this plate was exposed, the copper showed, but in 1784 George Cadman overcame this defect by soldering on an ornamental molding of solid silver. The electroplated imitations of Sheffield plate do not have such a molding. Genuine old pieces of Sheffield plate are much prized for the warmth of color and the excellence of the texture, which are far superior to those of electroplated objects. (See ELECTROPLATING.) Worn pieces of Sheffield plate are often repaired by electroplating, but when so repaired are valueless from the standpoint of museum or collector. In 1840 John Wright, a surgeon of Birmingham, discovered the electroplating value of a solution of cyanide of silver in cyanide of potassium, and the new and cheaper process soon crowded out the old one. Wright's patent was purchased by the Elingtons of Birmingham, who the next year erected large factories and inaugurated the development of the immense electroplating industry. Consult H. N. Veitch, *Sheffield Plate* (London, 1908).

**TABLEY, BARON DE.** See WARREN, J. B. L.

**TABOO'** (adaptation of Tongan, *tabu*, Polynesian *tapu*, forbidden, probably from *ta*, mark, and *pu*, an intensive adverb; Fiji *tambu*; Hawaiian *kapu*). An object or act religiously interdicted, and the religious system based upon such interdiction. Under various names the practice of taboo is found all over the earth, but it has nowhere else been so systematized as in Polynesia. Primarily taboo is something forbidden because the tabooed object is regarded as potent to injure, owing to its mana or mysterious (spiritual) power, which may be either holy, as a priest's possession, or unclean, as a corpse. There is at first no moral significance in taboo, and often the interdict is due merely to fear of evil spirits. Thus, in New Zealand there are a mana taboo and an atua taboo, the latter arising from a belief in spirits. Taboo also reverts frequently to another phase of primitive philosophy, which sees retained in blood, nails, hair, etc., though separated from the body, the spiritual power of the individual. But at times

taboo is merely the expression of conservatism which may be religious or social. An instance is the taboo of iron in religious ceremonies. Thus, both the ancient Romans and the modern Pawnee Indians put a taboo on iron, since the gods dislike innovations. Even without the fear of divinities the same religious conservatism prevents the Australians from using stone implements in circumcision, for which they employ the still more antique burnt-wood knife. But there is also a social conservatism resulting in taboo. Foreigners and new things generally are dangerous and are regularly tabooed by many tribes (as in Africa), though the taboo is easily removed except in the case of chiefs. In such cases the foreign person, thing, or act is tabooed because of the dreaded mana. But, on the other hand, there are taboos which are simply in the interest of old practices. Thus, the Hindu laws give the bed hours of kings, and it needs only the right environment of superstition and antiquity to make such laws seem to be the effect of taboo, as in Egypt, though this is not the case in India.

Taboo may be permanent or temporary, private or public. Especially stringent are all royal and priestly taboos, because kings and priests control the weal of the people and must be guarded against danger in food and the like. In some cases a king becomes a mere slave bound by the rules thus laid upon him. In others he makes taboos for his own interest. The people too must guard themselves from the mysterious divine mana of the king, and it is this latter aspect of taboo which king and priest alike find it for their interest to maintain.

What is not taboo is *noa* (common), and in this antithesis lies the germ of the conception of personal property. Thus, taboo became in many cases merely an assertion of proprietary rights, as may be seen from the fact that a lesser chief's taboo was disregarded in New Zealand by a stronger chief, but the latter's taboo was feared and respected by the former. Isolation was the object of taboo, and this was the first stage to ownership. Food taboos are often totemistic or hygienic, and the taboo of knots, which is very common, is a temporary taboo imposed because of the belief in mimetic magic. But it is not necessary that the imitative act be due to a wish to injure. Thus, in Africa, Greece, and elsewhere there is a taboo on knots, locks, crossed arms and legs—in short on all that suggests an impediment. Another common taboo is the *hlonipa* (name taboo) of the Kafirs, with the taboo of woman language found among the same tribes (as also among the Semites and the Caribs), certain names and words being tabooed, e.g., the names of fearful beasts in India, of kings in Africa, and of the dead in Australia and elsewhere, as well as words used only by women. Sex taboo is very common. Thus, the belief that a woman's blood is fatal to a man leads at stated periods to a temporary taboo of women even among civilized Hindus, and in many countries men may not eat with women. Other common examples of taboo are as follows: to be ill or to touch a corpse or grave, a king or a priest, or anything divine (such as royal blood) renders one taboo. A priest's or a king's clothes are so filled with mana that it would kill any one else to wear them, and to enter a chief's house or even in some cases to look at him would be destructive. A priest's house is taboo

even to himself, so far as eating in it goes. The taboo of part of one's self is often recognized. Thus, when a person is under taboo he may not touch his own head and has to be fed by another or eat with chopsticks. Such a person may not touch a drinking vessel lest he render it also taboo and dangerous; for whatever comes in contact with a tabooed object becomes itself tabooed. The private or public taboo of places for certain practical reasons is also noteworthy. A river is tabooed by a king until the fishing season is over, a wood till the game is caught, a field till the harvest is gathered. A public taboo is where, as in New Zealand, a whole community is made taboo while getting in their crops. This renders it impossible for any member of the tribe to do anything else till the taboo is removed and prevents any stranger from approaching the tabooed ground. The removal of a public taboo is made by a priest, who repeats a spell and performs certain rites over the tabooed people. If a chief wants anything for himself, he taboos it by calling it part of himself. Women, if of high rank, may taboo an object as effectively as do chiefs of the tribe.

Taboo has been explained either as a priestly trick or as a religious observance, required by the chief for political reasons. But neither explanation will suffice for most cases, while again some taboos are not religious at all. Others explain taboo as due to a categorical imperative and deduce from it all moral laws as well as most of the practices of civilized communities, such as caste, the wearing of ornaments, the carrying of umbrellas, the washing of newborn babes, etc. On the other hand oaths, the punishment of murderers and thieves, and marriage restrictions may be developed out of a taboo system, which recognizes no moral sin, only the danger of breaking taboo. But in that case we have to do not with a categorical imperative, but with a belief in a mysterious spiritual potency and the fear of its effect. An extension of this belief results in its becoming purely formal. Taboo itself, then, may be divided into purely religious and formal taboo; while, if everything forbidden is to be called taboo, there must be added a mass of detailed regulations arising from different sources, some of them having no connection with what is strictly called taboo; and it is evident that for such a combination of effects there can be no one explanation. Consult: Taylor, *Te Ika a Maui, or New Zealand and its Inhabitants* (2d ed., London, 1870); Gennep, *Tabou et totémisme à Madagascar* (Paris, 1904); W. G. Sumner, *Folkways* (Boston, 1907); W. Smith, *Lectures on the Religion of the Semites* (new ed., New York, 1907); J. G. Frazer, *The Golden Bough: A Study in Magic and Religion* (3d ed., London, 1907-13); id., *Taboo and the Perils of the Soul* (ib., 1911).

**TAB'OR.** The most conspicuous and famous mountain in Galilee (Map: Palestine, C 2). Its summit is 1843 feet above sea level. As a typical mountain of the Holy Land it impressed itself upon the language of poetry. It seems to have been the natural site for a sanctuary, and upon it from early times lay a town of the same name. Here Barak assembled his forces to attack Sisera (Judg. iv); twice the Jews held it, though unsuccessfully, against the Romans (53 B.C.: 67 A.D.). It is the traditional scene of the Transfiguration of Christ, although

most unreasonably, and so it became the site of churches and monasteries and was an object of pious pilgrimage. Consult: V. Guérin, *Description géographique, historique, et archéologique de la Palestine*, vol. ii (Paris, 1874); *The Palestine Exploration Fund Memoirs*, vol. i (London, 1881); L. B. Paton, *Descriptive Geography of Palestine* (New York, 1911); I. Ben-zinger, in Basdeker, *Palestine and Syria* (5th ed., Leipzig, 1912).

**TABOR** (OF. *tabour*, Fr. *tambour*, Sp. *tambor*, from Ar. *tambūr*, sort of lute with a long neck and six brass strings, drum). A small drum, played with one stick, generally in combination with a galoubet or three-holed fife.

**TABOR COLLEGE.** An institution for higher education founded at Tabor, Iowa, as an academy in 1857 and incorporated as a college in 1866. The founders were Congregationalists, whose desire was to establish a Christian college for young men and women who might be trained for lives of service. There are three departments—the college, the academy, and the conservatory of music. The college subjects are arranged in courses leading to the degree of A.B. The academy prepares for college instruction, and the conservatory offers musical training. The dean and acting president in 1915 was Nelson W. Wehrhan, Ph.B., B.D.

**TABORITES.** The more radical party of the Hussites in Bohemia. They derived their name from their fortress of Tabor, near the river Lužnič. They asserted the right of individual judgment, rejected ordinances of the Church not expressly appointed in the Bible, accepted only the sacraments of baptism and the Lord's Supper, and had democratic tendencies. Their leaders were John Ziska (q.v.), Nicholas of Pistna (Husinec), Procopius the Great, and Procopius the Lesser. (See PROCOPIUS, ANDREW.) At first, in the face of common danger, all parties of the Hussites held together and inflicted repeated defeats upon the Imperial troops. After the Calixtines (q.v.) had made terms with Sigismund and the Church (1433) the Taborites continued the war, but were overthrown at Běhmischbrod, May 30, 1434. The remnant of them was absorbed in the Bohemian Brethren (q.v.). See HUSSITES.

**TABRIZ**, tā-brēz', TAVRIS, or TEBRIS. The second largest town of Persia, capital of the Province of Azerbaijan, situated in a wide valley, on the Aji, a tributary of Lake Urumiah, 35 miles east of the lake, over 4000 feet above the sea (Map: Persia, B 3). Owing to the many earthquakes, large sections of the town are in ruins. The place is healthful, although the weather is cold a third of the year. In spite of the altitude the bare rocks rising on the northeast and east and the peak of Sahand standing on the south give Tabriz the appearance of being shut in by mountains. The squalor of the native huts and the poor sanitary precautions are counteracted by the abundance of water and the numerous refreshing orchards and gardens. Few buildings or ruins are of special note. There are about 100 public baths, numerous caravansaries, five Christian (Armenian) churches, and over 300 mosques. Among these the Blue Mosque (Masjid i Kebud), incrustated within and without with blue faience tiles, is especially worthy of mention. Before the Caucasus Railroad and the Caspian Sea became important mediums of transportation, and the Russian trade was diverted to

Astara and Resht, Tabriz was the emporium of Western trade. More than half the trade is with Russia. The imports are largely cotton and woolen tissues, sugar, and tea. The exports are chiefly carpets, dried fruit, hides, live animals, and raw cotton. The Russian carriage road from Julfa, on the frontier, to Tabriz (80 miles) was completed about the beginning of 1907. There are lead mines in the vicinity of Tabriz, and copper and cobalt are found in the Sahand. Pop., about 200,000.

Tabriz is said to have been founded by the wife of Harun al Rashid in 791, but is mentioned before that date. In 858, 1041 or 1042, 1721, and 1780 it was devastated by earthquakes. In that of 1721, 80,000 persons are said to have lost their lives. It was held in turn by the Arabs, Seljuks, Mongols, and Turkomans, from whom it was taken by the Persians. It was several times in the possession of the Turks and was finally taken from them by Nadir Shah in 1730. Tabriz was captured by the Turks and then by the Russians in the European War which began in 1914. (See WAR IN EUROPE.) Tabriz is essentially a Turkish city, and Turkish is the prevalent language.

**TABU.** See TABOO.

**TAB'ULA BANTI'NA.** The chief source of knowledge of the Oscan tongue—a bronze tablet in the Naples Museum, containing on one side an Oscan inscription (38 lines) referring to affairs of Bantia and on the other a portion of a law in Latin (32 lines). It was found near Bantia in 1793. See ITALIC LANGUAGES, *Oscan*.

**TAB'ULA CEBE'TIS.** See CEBES.

**TABULÆ EU'GUBINÆ.** See EUGUBINE TABLES; ITALIC LANGUAGES.

**TAB'ULÆ HERAC'LEEN'SIS.** See HERACLEA, 1.

**TABULA ILI'ACA** (Lat., Ilian Tablet). A small relief in soft marble found near the ancient Bovillæ in 1683 and now in the Capitoline Museum at Rome. The slab, 10 by 11½ inches, is covered with scenes in low relief from the Trojan War, taken from the *Iliad* and the poems of the Trojan cycle (see CYCLIC POETS), with explanatory Greek inscriptions. Some think it was intended for school instruction, others that it was an ornamental panel of a bookcase. Consult: Jahn, *Griechische Bilderchroniken* (Bonn, 1873); A. Baumeister, *Denkmäler des klassischen Altertums* (Munich, 1889); Th. Schreiber, *Atlas of Classical Antiquities*, plates xcii a, xciii (Eng. ed., by W. C. F. Anderson, New York, 1895).

**TAB'ULARIUM** (Lat., from *tabula*, board, tablet, record). A large building on the slope of the Capitoline Hill facing the Roman Forum, built by Quintus Lutatius Catulus in 78 B.C. for the preservation of state records. It rested on massive substructures and consisted of a series of vaults with an upper corridor, lighted through a series of arches flanked by Doric half columns, some of which are still to be seen. Its extent corresponded with that of the present Palazzo del Senatore, which is built on the ancient walls. The structure is in good preservation. Consult Christian Hülsen, *The Roman Forum* (Eng. trans., by J. B. Carter, 2d ed., Rome, 1909), and S. B. Platner, *The Topography and Monuments of Ancient Rome* (2d ed., Boston, 1911).

**TAB'ULAR STANDARD.** A proposed standard of value which should obviate dif-

ficulties due to changes in the purchasing power of money. The proposal involves the preparation, by public authority, of a table of relative values of certain selected commodities after the fashion of an index number and the permissive use of this table as a legal standard in contracts involving deferred payments. A tabular standard has been briefly defined as an official index number. Its compilation would require a commission or other body with power and facilities to collect price statistics. Having decided what commodities should be employed as basis for the standard, the commission would then calculate a yearly or monthly index number according to some accepted method. (See INDEX NUMBERS.) The statistics would of course be public, and any one who chose could verify the calculation. The rise and fall of prices would either be expressed in percentages, or an arbitrary unit would be adopted whose changing values, expressed in money, would indicate the same thing.

The practical operation of the tabular standard is simple. When a person makes a loan of, say, \$100 for one year, the contract entitles him to receive the same number of dollars (usually with interest) at the end of the specified time, but it does not insure that the \$100 which he lent and the \$100 he receives will have the same purchasing power. If prices have risen in the interval, his \$100 will buy less; if prices have fallen, it will buy more. In so far as changed purchasing power is not compensated by a change in rates of interest, debtors are likely to be burdened by an appreciation, creditors by a depreciation, of the value of money. Suppose, however, the tabular standard to be employed, and that A sells a piece of property to B for \$12,000, of which one-fourth is to be paid at once and one-fourth more at the end of each succeeding year. The \$3000 cash is, of course, paid as such. But after a year the tabular standard might show the purchasing power of money to have fallen 10 per cent. Expressed in tabular units, if at the time of sale a unit was worth \$10, it would now be worth \$11.11, giving the proportion 10.00:11.11:: \$3000; \$3333.33, which last figure is what B will have to pay. If at the end of the second year a unit of the tabular standard was worth \$9, B would be called on for only \$2700. Whether he pays more or less in money, the sum will always have a uniform value in terms of the commodities on which the standard is based.

That many advantages would be gained from the use of a tabular standard has generally been admitted. Two serious practical difficulties stand in the way of its introduction. First, the conservative attitude of business men towards any change of this sort; second, the difficulty of agreeing upon the precise mode of calculating the standard, and especially upon the precise commodities which should be selected as basis.

The first conception of a general index number or tabular standard, however, appears to date from 1798, when Sir George S. Evelyn read before the Royal Society a paper on "Endeavors to Ascertain a Standard of Weights and Measures." (*Philosophical Transactions*, vol. lxxxviii, pp. 175 et seq.) Evelyn's selection of articles is open to criticism, as was pointed out by Arthur Young in 1811. Joseph Lowe (*The Present State of England*, London, 1822), referring to both Young and Evelyn, proposes the actual

introduction of a tabular standard and discusses the modes of calculating it. (New York ed., 1824, p. 287, and Appendix.) His is the first practical treatment of the subject in English. In Germany the principle of the tabular standard had been suggested about 1805, in application to rent payments. (Horton, *Silver and Gold*, 1877, pp. 39, 157.) G. P. Scrope, in a pamphlet of 1833 and in *Principles of Political Economy* (London, 1833, pp. 405, 424), again proposed the standard. G. R. Porter also treated the subject and gave a table in his well-known *Progress of the Nation* (London, 1838, 1847). The matter was finally brought to prominence by W. S. Jevons, in an essay of 1865, and more forcibly in his *Money and the Mechanism of Exchange* (1875, chap. xxv).

Consult the *Reports of the Committee of the British Association on Measuring Variations in the Value of the Monetary Standard* (*British Association Reports*, 1887, 1888, 1889, 1890; the most important material in English); *Report of the Monetary Commission of the Indianapolis Convention*, 1898; also Walker, *Money* (New York, 1878); Price, *Money and its Relation to Prices* (London, 1896).

**TAB'ULA'TA** (Lat. nom. pl., tabulate, floored, table-shaped). A suborder of fossil corals characterized by the development of distinct horizontal septa or tabulae across the visceral chambers of the corallites. It includes such genera as *Favosites*, *Pleurodictyum*, *Micelania*, *Aulopora*, *Syringopora*, and others which are important members of the Paleozoic faunas. See CELENERATA; CORAL; and articles on the genera.

**TABULATING MACHINES.** See CALCULATING MACHINES.

**TACAHOUT**, ták'ká-hout' (native name). The small gull formed on the tamarisk tree, *Tamariscus indica*. Tacahout contains a large proportion of gallic acid.

**TAC'AMAHAC'** (South American name), or TACAMAHACA. A name applied to several varieties of oleoresins. One sort of tacamahac is yielded by the balsam poplar (*Populus balsamifera*) growing in the United States. Another variety is obtained from certain tropical American trees (*Elaphrium tomentosum* and *Elaphrium tacamahaca*). East Indian tacamahac is obtained from the *Calophyllum calaba*, *Calophyllum inophyllum*, and *Calophyllum tacamahaca*. These and certain other varieties are used in making varnishes and to some extent also in medicine. See CALOPHYLLUM.

**TACANA**, tà-ká'ná. A group of tribes, constituting a distinct linguistic stock, inhabiting the banks of the Upper Beni and Mamore rivers, northeastern Bolivia. They are remarkable for their light complexion, fine features, and independent expression. See ARAUNA. Consult D. G. Brinton, *Studies in South American Native Languages* (Philadelphia, 1892), and A. Groeteken, in *Anthropos*, vol. xi (Salzburg, 1907).

**TAC'CA** (Neo-Lat., from the Malay name). A genus of large perennial tuberous-rooted plants of the family Taccaceae. The few species are found in maritime places and woods in the South Sea Islands, tropical Asia and Africa. Some of them (*Tacca pinnatifida*, etc.) are much cultivated for their starchy tubers, which are used as food, their acidity being removed by maceration with water. They yield taliti arrowroot, used as a substitute for West Indian arrowroot. The leafstalks of various species

are boiled in China and Cochin-China and used as food. Hats, brooms, and other articles are made from the leaves.

**TACHÉ**, tá'shâ', ALEXANDRE ANTONIN (1823-94). A Canadian Catholic archbishop, born at Rivière du Loup, Lower Canada (Quebec), and educated at Quebec and Montreal. He joined the Order of Oblate Fathers, traveled great distances in the region of the Great Lakes and the northwest, became known for his mission work among the Indians, and founded several schools, colleges, and convents. In 1853 he became Bishop, and in 1871 Archbishop, of St. Boniface, Man., and he founded the Catholic theological college in that town. He wrote *Vingt années de missions dans le nord-ouest* (1866), and *Esquisse sur le nord-ouest de l'Amérique* (1869), which has been translated into English and is one of the most valuable works of reference on that region. Consult J. C. Dent, *Canadian Portrait Gallery* (Toronto, 1880).

**TACHÉ**, SIR ETIENNE PASCAL (1795-1865). A Canadian statesman. He was born at St. Thomas, Quebec, and served in the militia during the War of 1812. He afterward studied medicine and practiced his profession until 1841, when he was elected to the Canada Legislative Assembly. He was successively Commissioner of Public Works, Deputy Adjutant General of Militia, and member of the Legislative Council in 1848; Receiver-General in the Lafontaine-Baldwin ministry (1849-51) and in the Hincks-Morin and MacNab-Morin ministries (1852-56); and was appointed Speaker of the Legislative Council, retaining the receiver-generalship. He became Premier in the Taché-Macdonald ministry in 1856, but the real head of the government was John A. Macdonald, the Conservative leader in the Lower House. Taché retired from the premiership in 1857, but later formed in 1864 the second Taché-Macdonald ministry, combining the offices of Premier and Receiver-General. At this time political life was at a deadlock and old party lines had been practically obliterated. For the course of events preceding the historic gathering in 1864 at the city of Quebec, where Confederation was discussed and resolved upon, see CANADA, *History*. Of this conference Taché was elected chairman. In 1858 he was knighted. Consult J. C. Dent, *Canadian Portrait Gallery* (Toronto, 1880), and ib., *The Last Forty Years* (ib., 1881).

**TACHI.** See YOKUTS.

**TACHINA FLY**, tû-kí'ná (Neo-Lat., from Gk. *ταχὺς*, *tachys*, swift). A parasitic fly of the family Tachinidae. These insects resemble in general the common house fly and as a rule are gray, sometimes striped. They are usually parasitic upon caterpillars, upon the backs of which the females lay their eggs. The maggots penetrate the body of the victim and feed upon its soft internal organs. Frequently, however, caterpillars cast their skins before the eggs hatch. Tachina flies are considered beneficial to man.

**TACHYCARDIA**, ták'i-kär'dí-á. See PULSE.

**TACHYGENESIS**, ták'i-jén'ê-sis (Neo-Lat., from Gk. *ταχὺς*, *tachys*, swift + *γένεσις*, *genesis*, origin, generation). A term proposed by Hyatt for rapid evolution, or evolution by leaps, i.e., without the vast series of intermediate forms postulated by Darwin. Hyatt defines tachygenesis as "the law of acceleration in the inheritance of characters." It has been found

that characteristics are inherited in a series of species in a given stock at earlier and earlier stages in the ontogeny of each member of the series. These characteristics, as a rule, altogether disappear from the ontogeny, through lapse of heredity in the last members of a series, and thus the terminal forms become very distinct in development. Rapid evolution was also marked at the beginning of the evolution of any stock. In the dawn of geological history, as soon as divergent evolution set in, each type had a more or less free field, and its first steps in evolution were obviously not affected by natural selection. Afterward evolution became much slower. On the other hand, when the type began to decline there was a sensible quickening of evolution. Dall suggested the term "saltatorial evolution"; Galton, De Vries, and others, and especially the paleontologists, have all supposed that evolution has often been by leaps or spurts. Consult W. H. Dall, "On a Hypothesis of Saltatory Evolution," in *American Naturalist*, vol. xi (Boston, 1877), and A. V. Hyatt, "Cycle in the Life of the Individual (ontogeny) and in the Evolution of its Own Group (phylogeny)," in *Proceedings of the American Academy of Arts and Sciences*, vol. xxxii (ib., 1897).

**TACITUS**, tās'itūs, MARCUS CLAUDIUS (c.200-276). Roman Emperor (275-276). He was born at Interamna (modern Terni), in Umbria, and was elected Emperor by the senate after the death of Aurelian and an interregnum of seven months (275). He began his brief reign of 200 days at the advanced age of 75 years. He instituted needful reforms and favored the restoration of the power of the senate. His victory over the Alani and the Goths, for which he took the title *Gothicus Maximus*, is recorded on his coins. He was murdered by the soldiers in Asia.

**TACITUS**, PUBLIUS CORNELIUS (c.55-c.117). A Roman historical writer. His training and career indicate that he belonged to a Roman family of good standing. He was praetor in the reign of Domitian and consul suffectus under Nerva. In 78 he married the daughter of Gnaeus Julius Agricola (q.v.), a man prominent as a soldier and statesman. This event had great influence on his subsequent career. After his praetorship he was absent from Rome for at least four years until after 93, the year after the death of his father-in-law. The intimacy of Tacitus and Pliny the Younger is proved by references in the letters of the latter, and the two were associated in the successful prosecution of Marius Priscus, proconsul of Africa, charged with extortion. Tacitus' *Annals* were published in 116 or 117, so that we may believe that he lived to the reign of Hadrian. Apparently he looked forward to writing a history of the reign of Domitian and of that of Trajan, but he must have changed his plan, for he began his *Histories* with Galba and continued the work through the reign of Domitian. In the *Annals* he declares his purpose of writing the history of Augustus and in the *Histories* his design of narrating the reigns of Nerva and Trajan, but we have no indication that he ever carried out these contemplated tasks. He wrote, however, the history of the empire from the death of Augustus down to the beginning of his earlier work, i.e., through the reign of Nero.

The earliest extant work of Tacitus is the *Dialogus de Oratoribus*, published about 75, or somewhat later, but not later than the reign

of Titus. The *Agricola* followed in the year 98. Even when engaged upon these books the historian was preparing for some greater work. It is possible that his *Germania*, or more fully *De Origine, Situ, Moribus, ac Populis Germaniae*, represents some of the material accumulated in preparation for a more extensive history. The *Histories* belong to the reign of Trajan. The *Annals* are the last work of the historian. As we have references to the *Annals* in the *Histories*, the date must be later than 108, and, as there is apparently a reference in the second book to Trajan's conquest in the East (115-116), the publication may have been just prior to the reign of Hadrian. The *Dialogue on Oratory* belongs to the writer's early manhood, and gives evidence of the influence of Cicero and Quintilian, in so marked a degree that some scholars have attempted to assign it to Quintilian or to some other author not identified. The best opinion of the present day, however, is in favor of the genuineness of the work. Different as the work is on the surface from the *Annals*, it is yet possible to see in it the beginnings of the style so characteristic of Tacitus' latest work. The subject is an investigation into the causes of the decline of eloquence, and the discussion is carried on by two celebrated orators of the Flavian period who are respectively supporters of the old and of the new oratory. The *Agricola* is a gem, a most carefully prepared piece of biographical composition. The rhetorical power of the writer is plainly felt in the closing chapters, which are unexcelled in Latin literature. His *Germania* is a most important work because of its descriptions of political institutions and of the customs of various tribes. As the writer brings into vivid contrast the life of the Germans and that of the Romans, it has been thought by some that he was endeavoring to instruct his countrymen, either by pointing out their evil ways, or by startling them and warning them against the dangers threatening on their northern frontier. Tacitus shows an exact knowledge of those Germans near the Rhine, but is uncertain as to the interior and more remote tribes. The greatest work of Tacitus has not come down to us entire, for of the *Histories* there are extant only the first four books and a part of the fifth, so that we have merely the year 69 and a part of 70. Of the *Annals* there is extant only about one-half, and this does not give a continuous narrative. After the fifth chapter of the fifth book there is a lacuna which marks the loss of the events of 29-31. Tacitus probably ended this book with the death of Sejanus, so that the beginning of the sixth book is also lacking. The seventh to the tenth, the beginning of the eleventh, and the close of the sixteenth are also missing, and we thus lose all of the reign of Caligula, the first five years of Claudius, and the last two years of Nero.

In the *Annals* Rome and the Princes form the centre about which are grouped the events of a history which is not that alone of Rome, but of the associated provinces. The Medicean manuscript designates the work *Ab Excessu Divi Augusti*, and this is no doubt the original title. In the *Histories* Tacitus writes as a contemporary, and therefore with a surer touch, and he gives full play to his dramatic powers in his description of what is quite familiar to him. The *Annals* represent the culminating task of his lifetime and are the work of the period of his full development as a writer.

The great power of Tacitus as an historian is due to his skill in discerning the motives which lead men to act, his deep psychological insight. He studies men, not things, and hence he is skilled in character painting. A marked feature of the Tacitean spirit is the tendency to impute a base or unworthy motive to all the actions of those men whom he describes. This is particularly true of his treatment of Tiberius. Certain it is that Tacitus writes of Roman society as a pessimist, and we may obtain a juster view by turning to the more attractive picture presented by his friend and contemporary Pliny the Younger.

There are three distinguishing features of Tacitus' style—conciseness, variety, and poetical coloring. There is not a superfluous word, and his condensation sometimes causes obscurity. We may say that his conciseness corresponds to his thought, for there is nothing artificial in it, and the style is characteristic of the writer. Here he was influenced by study of Sallust (q.v.) and Thucydides (q.v.). Tacitus' fondness for variety is found in his word positions, and in his variation in forms and constructions. The poetical coloring came from his study of the Augustan poets, particularly Vergil. Many words and expressions may be traced to Vergil, particularly in the minor writings and the *Histories*.

Important manuscripts of Tacitus are the Codex Mediceus (I), dating from the ninth century and containing a part of the *Annals*; and the Codex Mediceus (II) of the eleventh or twelfth centuries, containing what remains of the other books of the *Annals* and the *Histories*. The *Germania* and *Dialogus* are obtained from a manuscript in the Vatican based on an earlier one of the ninth century and again from a manuscript at Leyden, dating from the fifteenth century. The *Agricola* is found in two transcriptions of the fifteenth century, now in the Vatican. The *editio princeps* is by Puteolanus of Milan, about 1476. The best text is that of C. Halm in the "Teubner Series" (Leipzig, 1886). Important editions are the *Annals*, with English notes by H. Furneaux (Oxford, 1891-92; vol. i, 2d ed., 1896); Allen, *The Annals of Tacitus*, i-vi (Boston, 1890); Codley, *The Histories* (New York, 1891); Spooner (London, 1891); Frost, *Agricola and Germania* (ib., 1891); Hopkins, *Agricola and Germania* (Boston, 1893); Furneaux, *The Agricola* (Oxford, 1896); Gudeman, *Agricola and Germania* (Boston, 1900); id., *Dialogus* (ib., 1894; 2d ed., in Ger., Leipzig, 1915); Peterson, *Dialogus* (Oxford, 1893); Furneau, *The Germania* (Oxford, 1894). Consult also: A. Draeger, *Ueber Syntax und Stil des Tacitus* (3d ed., Leipzig, 1882); Gaston Boissier, *Tacitus and Other Roman Studies* (New York, 1906). The lexicons for Tacitus are Boetticher's (1832) and the great work of Gerber and Greef (completed 1903). An excellent English translation is that by Church and Brodribb (London, 1876-77); a translation of the *Dialogus*, *Agricola*, and *Germania* by W. Peterson and M. Hutten forms one of the volumes of the Loeb Classical Library (New York, 1914). Consult the introductions to the editions of the *Dialogus* by Peterson and Gudeman; Martin Schanz, *Geschichte der römischen Litteratur*, vol. ii, part ii (3d ed., Munich, 1913); W. S. Teuffel, *Geschichte der römischen Litteratur*, vol. iii (6th ed., Leipzig, 1913); M. S. Dimsdale, *A History of Latin Literature* (New York, 1915).

**TACK.** See NAIL.

**TACKING** (from *tack*, from OF. *taque*, *tache*, dialectic Fr. *tache*, nail, tack; so called because of the part of the sail to which the rope is attached) AND **WEARING** (from wear, AS. *we-rian*, Goth. *wasjan*, OHG. *werjan*, to clothe; con-

neeted with Lat. *vestis*, Gk. *ἔσθῃς*, *esthēs*, clothing, Skt. *vas*, to put on clothing). A vessel is said to be on the starboard tack when she is sailing with the wind on her starboard side, and on the port tack when the wind is on her port side. She is close-hauled on either tack when she is sailing as near to the wind as the set of her sails permits. The operation of changing from one tack to the other is called tacking if the vessel comes up head to wind and then falls off on the other tack, and wearing or gybing if

she falls off—bringing the wind astern—and then comes up to the wind on the new tack.

It is evident from the sketches that in tacking there is a gain to windward, if the vessel is a weatherly one and well managed; while in wearing there is a loss, because part of the time the

ship is running away from the wind. Therefore tacking is always preferred when practicable. While all properly built vessels will tack under ordinary conditions of sea and wind, there are times when the sea is very rough and the wind so strong that little sail can be carried; or the wind may be too light to give sufficient headway for tacking; or the vessel may be improperly sparred or ballasted. In these cases wearing is necessarily resorted to. In vessels carrying fore-and-aft sails only, the operation of tacking requires little labor, but in square-rigged ships the yards must be swung and the sails adjusted on the new tack. Wearing is called gybing when the vessel is fore-and-aft rigged and carries a boom mainsail which is not taken in or lowered during the operation. It is evident that when the wind, in wearing, passes from one side to the other of such a sail it will give a thrust of considerable violence, and this thrust must be carefully watched in small vessels—and in large ones if the wind is strong—or it may cause them to capsize.

Tacking is frequently called going about. While the operation is in progress a vessel is in stays; if she fails to tack and falls back on the same tack as before, she is said to miss stays. A lively, fast-moving vessel, particularly if deeply loaded, will, before losing way, shoot some distance directly up into the wind after it is out of her sails. Advantage is frequently taken of this fact to avoid some slight obstruction, when tacking is undesirable or otherwise unnecessary, and the operation is called making a half board. To make a good board is to lose nothing to leeward; to make short boards is to tack frequently; to make sternboard is to go astern.

**TACKING OF MORTGAGES.** The act, permitted by a doctrine in English equity practice, of one who takes a mortgage or lien on real property subsequent to a second or later mortgage and purchases the first mortgage and merges or tacks his security in it. The effect of this is to compel the intermediate incumbrancers to redeem the first mortgage, including the one thus merged with it, before they can enforce their liens. The application of the doctrine in the United States is restricted to cases where the subsequent mortgagee buys in the first mortgage without actual or constructive knowledge of the existence of the intervening lien. Consult authorities referred to under **REAL PROPERTY**.

**TACKLE** (MDutch, Dutch, LG. *takel*; possibly connected with Icel. *taka*, AS. *tacan*, to take, Lat. *tangere*, to touch). A combination of blocks and ropes designed to increase the capacity of the available power to move heavy weights or decrease the time required to move an object with a power capable of moving only at a certain speed. The block consists of a shell or frame containing one or more sheaves or pulleys and a strap to attach the block to the weight or support. It is evident that in all cases one block of a tackle, or one end of the rope—if there is a single movable block—must be fixed. This being the case, in simple purchases and neglecting friction we have  $P = \frac{W}{N}$ , in which  $P$  is the power,

$W$  the weight, and  $N$  the number of parts of rope at the movable block. The amount of power lost by friction depends upon many things, such as the character of the rope, its size with reference to the diameter of the pulley and the weight to be raised, the condition of the at-

mosphere, the bearings of the pulleys, etc. But in ordinary tackles, with the usual type of

FIG. 1.

A, single whip; B, runner; C and D, gun tackles.

pulleys, rope, etc., the loss by friction is estimated at about one-sixth the gain effected by

FIG. 2.

called, are shown in the accompanying figures. See **BLOCK**; **PULLEY**.

**TACLOBAN**, tāk-lō'bān. Capital of the Province of Leyte (q.v.), Philippine Islands (Map: Philippine Islands, E 5). The town, which is on the east coast, is well built and has an important trade. The port is well protected and has four different wharves. Pop., 1903, 11,948.

**TACNA**, tāk'nā. The northernmost province of Chile (Map: Bolivia, C 7). Area, 9248 square miles. Its level and arid interior is inclosed by the slopes of the Andes on the east and the coast range on the west. The rainfall is scanty and, excepting river valleys, the interior is an arid desert. The climate is unhealthy and earthquakes not infrequent. There are deposits of nitrate, silver, and copper, which are mined to a limited extent. Pop., 1912, 44,291; concentrated chiefly in the capital, Tacna (q.v.), and the port Arica (q.v.). The province formerly belonged to Peru and was ceded to Chile for ten years in 1884. At the expiration of that period, according to the provisions of the treaty, the ownership of the province was to have been determined by a plebiscite of the inhabitants. At the end of the 10 years disagreement as to the manner of taking the plebiscite prevented a settlement of the question, and all efforts towards adjustment have ended in failure.

**TACNA**. The capital of the Province of Tacna, Chile, in the northwestern part of the province, about 40 miles by rail from Arica (Map: Bolivia, C 7). It was formerly a place of considerable commercial importance with notable municipal and industrial establishments, but the construction of railway lines in the Province of Antofagasta diverted the trade southward. Pop., 1907, about 15,000. During the Chilean-Peruvian War a battle took place near Tacna on May 26, 1880, in which the Chileans defeated the allied Peruvian and Bolivian forces.

**TACOMA**. The county seat of Pierce Co., Wash., at the head of Commencement Bay, Puget Sound, 28 miles south of Seattle (Map: Washington, C 3). It is the terminus and western headquarters of the Northern Pacific Railway. The Great Northern Railway, the Chicago, Milwaukee, and St. Paul Railway, and the Oregon and Washington Railroad and Navigation Company (Union Pacific) also enter the city. Numerous steamship lines, including several transpacific lines, make it a port. Tacoma has an attractive situation, rising about 300 feet above the sea level. It is particularly a city of homes. The Olympic Mountains on the west, the Cascade Mountains on the east, and Mount Rainier, also known by the Indian name, Tacoma (14,408 feet), 60 miles to the southeast, afford beautiful mountain views. The principal buildings include the United States Post Office, customs and judicial building, the city hall, county courthouse, the National Realty, Fidelity, and Tacoma office buildings, and the Tacoma Hotel. Other public buildings are the State Historical Society and Ferry Museum of Art. Among the educational institutions are the College of Puget Sound (co-ed. Methodist Episcopal), the Annie Wright Seminary, an endowed school for girls (Protestant Episcopal), and the Pacific Lutheran University. The public schools include 2 high schools and 35 grade schools, with an enrollment of 15,338. Adjoining one high school is a steel and concrete stadium seating 30,000. The hospitals include the Tacoma General, St. Joseph's, Northern Pacific and County hospitals. There are 1090 acres in public parks, 191 miles of

paved and 291 miles of graded streets. The average rainfall is 36 inches. Excellent transportation facilities both by land and sea and a vast and highly productive tributary country have made Tacoma a leading business centre of the Pacific coast. The factories number 408, employing 11,557 at an average monthly pay roll of \$787,000. Coal in abundance is mined but a few miles away, and there are rich agricultural and timber lands near by. Tacoma has a large wholesale trade, as well as large manufacturing industries and extensive coastwise and foreign commerce. The principal articles of commerce are lumber, wheat, flour, coal, coke, fish, and fruit. In 1913 the census of manufacture showed \$25,000,000 of capital invested in industries and products valued at \$59,000,000. The chief industries include lumber, furniture, flour, foundry and machine-shop products. There is also a large smelter, and the Northern Pacific car shops are located here.

Tacoma has the commission form of city government, with a mayor and four commissioners. The city revenues for 1914 include general receipts, \$1,155,122; city dock, \$33,968; water department, \$451,056; light department, \$632,349; local improvements, \$892,117. The city owns its own gravity water system and light and power plant. The total value of property owned by the city is \$26,000,000.

The present city of Tacoma was organized in 1883 by the consolidation of Old Tacoma (1868) and New Tacoma (1874). Pop., 1890, 36,006; 1900, 37,714; 1910, 83,743; 1915 (U. S. est.), 108,094; 1920, 96,965.

**TACOMA, MOUNT.** A peak of the Cascade Range. See RAINIER, MOUNT.

**TACONIC MOUNTAINS, or TAGHKANIC MOUNTAINS.** A low mountain range on the east boundary of New York State and occupying a small area in Massachusetts and Vermont (Map: Massachusetts, A 2, 3). It extends from the Highlands east of the Hudson in a north-northeast direction, becoming gradually higher as it enters the northwest corner of Massachusetts, and passes into southwest Vermont, where it connects with the Green Mountains. Its highest peaks are Mount Equinox in Vermont, 3816 feet, and Greylock (q.v.) in Massachusetts, 3505 feet. It consists chiefly of metamorphosed Cambrian and Silurian rocks, to which it has given the name Taconic System (q.v.).

**TACONIC SYSTEM.** A name applied by Emmons in 1842 to a series of rocks found in eastern New York, western Massachusetts, and Vermont, and considered by him to be of pre-Potsdam age because of their metamorphosed character and the supposed absence of fossils. It was afterward shown that the formations were really the equivalents of the normal Cambrian and Ordovician strata in the adjoining undisturbed areas, so that the name has fallen into disuse. Consult Emmons, *Geology of New York*, part ii (Albany, 1842), and Dana, "A Brief History of Taconic Ideas," in *American Journal of Science*, third series, vol. xxxvi (New Haven).

**TACTICS** (from Gk. *taktikós*, *taktikos*, relating to arrangement, especially in war, from *taktós*, *taktos*, arranged, from *τάσσειν*, *tassein*, to arrange), **MILITARY.** From the eighteenth century until 1870 the word "tactics" was accepted to mean the art of giving battle, and included the plans of commanding and other generals on the one hand, and the execution of these plans by the troops on the other. This defini-

tion still holds; but it is nevertheless true that in the general case, since 1870, tactics are held to mean the execution of the dispositions furnished by strategy, whether on or off the battlefield. General tactics are distinguished from the tactics of the respective arms. Further, the subject is subdivided into as many branches as there are modes of activity by troops. Thus we have march tactics, combat tactics, supply tactics, etc.; we shall consider combat tactics alone, omitting also the history and evolution of the subject.

When used alone the word means battle tactics, or, as often put, the tactics of the three arms. Grand tactics and minor tactics are sometimes mentioned, meaning respectively the operation of great units, as divisions and corps, on the one hand, and those of smaller bodies on the other, such as would naturally carry out minor operations. But this division is not recommended. The following development of the subject applies, save when otherwise indicated, more to the open battlefield than to the conditions that prevailed in France and Flanders during the great war. These conditions, while greatly increasing the intensity of artillery and of infantry action, at the same time localized their effect both tactically and topographically.

#### TACTICS OF INFANTRY

Infantry, except during a single period, the Era of Knights or the Age of Chivalry, has always been the principal arm, that is to say numerically the strongest, and in its action the most decisive; ever since the introduction of firearms it has been gaining in importance. It is the only arm which can act independently, that is, without the assistance of the other arms, under all conditions of ground, weather, and other circumstances, in attack or defense, while in motion or when at rest, in closed or open order, with fire action or shock action; it can operate on all kinds of ground; it is more independent of circumstances than other arms; movement and effective firing may be combined to a far greater extent than in other arms; it can come into action more easily and readily, it is equally effective in attack and defense; it is more easily and cheaply equipped and maintained than other arms; and it can be more quickly made efficient. But it is limited in rate of movement, hence the advantage of combining cavalry with it; and in the range of effective action, hence the advantage of combining artillery with it for battle and cavalry for reconnaissance.

Infantry holds its high position mainly on account of its great fire action combined with its capacity to utilize fully the configuration of the ground. The fire of the present breech-loading rifle begins to make itself felt at 2500 yards, but does not become effective as aimed fire until about 1000 yards from the enemy; at 500 yards it is decisive, and at 300 practically annihilating. Constant improvement gradually increases these distances, and in the Boer War it was noticed that the British attack usually came to a standstill at 900 yards. The perfection of firearms and the more extended utilization of the configuration of the ground have greatly increased the power and significance of fire action. The introduction of an automatic firearm is now only a question of a short time, and this will still further increase fire effect.

The bayonet attack comes into play only under special conditions, to confirm the results of previous fire action. The latter takes the longer time and makes the highest demands on strength and endurance; moreover, its annihilating effect punishes promptly any rash resort to the bayonet. Nevertheless the necessity for the bayonet remains; not always in hand to hand conflict, but as a threatening measure in the assault of a position, and because of the confidence it inspires and the power of initiative it confers.

The power of infantry fire necessitates cover, and the utilization of the natural configuration of the ground to secure this has acquired vital importance. The crossing of open spaces is avoided as much as possible, or postponed to decisive moments; hence the battle usually crystallizes around woods, villages, and groups of buildings. But in broad open fields, or where troops are opposed in strong natural or artificial positions for a considerable time, artificial cover must be obtained, consequently intrenchment is resorted to, and an intrenching tool is necessary for the soldier's equipment.

The formations in which infantry moves and fights are not the result of haphazard theory. Infantry can fight only when the distance from the enemy or the available natural or artificial cover permits it to fire, and effective fire can be obtained only when the soldier has room to use his arm freely, consequently this arm fights in open or dispersed order, the closed order being used only for troops in rear of the firing line. The greatest difficulty in leading infantry is the loss of control by the officers due to this dispersed order, and this can be overcome only by training, discipline, drill, and the example of the officers.

The tactics of infantry are designed to facilitate, as far as possible, that great object of every commander—to make himself stronger than the enemy at the time and place of actual combat. This can be done only by preserving unity of command, concerted action, and mobility, combined with the least exposure to loss. The formations in use attempt to fulfill these conditions, and the main principles governing in modern infantry tactics are: individual training and instruction to develop a high degree of initiative combined with perfect subordination; the greatest development of fire in the firing line; a subdivision into fire units of such strength as to insure complete fire control by commanders; in the attack, pressure against the flank combined with a frontal attack; the reinforcement of the firing line by a succession of lines gradually closing to the front; and, if possible, the accumulation of a greater depth of forces opposite the portions of the enemy where the attack is to be concentrated.

The front line in the attack is composed of the fighting line and its reserve, and the former is subdivided into the actual firing line and its supports. The battalion is the tactical unit, and the front it covers, as well as the particular nature of the action, determines the number of companies it places in the fighting line. The battalion covers normally about 400 yards of front and a company about 100 yards. The progress of the attack will proceed in general outline as follows: before entering the zone of artillery fire (or at about 3000 yards) each regiment forms from column of march into line; the battalions then designate the companies to

form the fighting line and those to form the reserve; the companies of the fighting line then designate the sections for the firing line and for the supports. Within effective infantry fire the column must deploy, since the bullet from the modern firearm can pass through two men at 1500 yards, and at 400 yards it can go through four men, so that the column, if preserved here, must expect heavy losses. The successive lines, deployed in open order or in company column of sections, depending on the effect of the enemy's fire, continue to advance. When within effective range fire is opened by volleys, or a designated number of rounds at will, the skirmishers halting to deliver their fire, then advancing. In open country, within 1100 yards skirmishers can no longer remain standing. The supports gradually close on the firing line, deploy as skirmishers and begin to reinforce the firing line. Then begins the advance by rushes, by alternate subdivisions, and portions of the reserve are added to the firing line, the rest still held in reserve in rear of the point of main attack. The final act is the charge, the reserves being brought up to insure victory and hold the position. The engagement is in general decided at about 900 yards' distance.

One of the principal conditions for the success of the attack is that fire once opened should be kept up to about the same strength, and this again indicates the necessity for comparatively weak lines at first; on the other hand, the enemy should be met with superior forces from the beginning, and this superiority kept up. Between these two limits the commander must decide.

Decisive action is usually sought on a flank, but not necessarily an extreme outer flank of the line, for a modern line, from various causes, may have a number of inner flanks, which are also points of weakness. Early in the engagement the enemy must be forced to unveil his position, and then these interior flanks can be determined, and the commander may decide where to concentrate forces, for superiority is desired only at decisive points. The rest of the front can be held by comparatively weak forces. This also indicates the necessity for keeping as many troops as possible in reserve; but it must be borne in mind that the requisite number to insure superiority must be put in the firing line from the beginning, and this apart from all other considerations. The reserves must be added to the firing line in dispersed order, for the commander who hopes to force a decisive action by means of reserves in closed order disregards the effects of modern firearms. In an ideal action all the rifles are in use at the decisive moment, but this is not possible in long lines. Still the troops remaining in close formation will find other uses. To cover a retiring skirmish line only those reserves can be used that stand far enough to the rear to be readily placed in a defensive position to which the line may fall back; if they are already on the way to the front they had better be thrown into the skirmish line, to turn the tide, if possible.

Breaking through the front of a line is a very difficult undertaking and hardly possible to-day. Consequently the reserves should not be in rear of the centre, because they are of no use there, and would have to be kept so far in rear, to avoid the effects of the enemy's fire, that they might not enter the action in time. Their place

is on one or both flanks, and so far beyond the flanks that they can enter the fight by a simple, direct forward movement, without any lateral gaining of ground. A regiment held in reserve, e.g., should be placed in rear of the flank and about 600 yards beyond it. The main reserve is always behind the flank where the decisive action is expected to be brought about.

The regimental commander can assign to each battalion only its general duty; the execution must be left to the battalion commanders. On the defensive he assigns to each his section of ground, on the offensive his point of attack. A skirmish line fires only when at a halt, and the position taken depends on the range, but lying prone is now regarded as best because it gives the enemy's artillery no opportunity to get the range. Before opening fire the distance must be estimated, a difficult matter even for those well trained in time of peace. The skillful designation of the target also requires much practice. The firing may be by volley or at will, the former being advantageous when the range has been determined and the ground is suitable for observation of the fire, but in general is merely a drill-ground exercise of little practical use. The conduct of the fire and all fire control is in the hands of the company and subordinate commanders, and one of the most difficult duties of these officers is the observation of the effects of the fire.

#### TACTICS OF CAVALRY

The prominent characteristic of cavalry is rapidity of movement, and its greatest duty is the service of security and information: a cavalry which is superior to the enemy's in screening its own army and clearing up that of its adversary will more than pay for itself. Its duty next in importance is pursuit, as it alone is capable of overtaking and holding a retreating enemy till the arrival of the infantry. On the battlefield its use is important, but limited. Cavalry is the arm of surprise, of sudden and vigorous attack; but its power of defense is comparatively poor, consequently it cannot hold for any length of time the ground it has gained. It is greatly dependent on the configuration and character of the ground, and its use in conjunction with the other arms is limited to favorable movements. Cavalry for most effective action requires broad, open country, rarely available on modern battlefields. For this reason, and on account of the increased range, rapidity of fire, and accuracy of firearms, cavalry can seldom decide battles. Surprise is to-day absolutely essential for the success of a cavalry attack, but to seize the proper moment is difficult, and requires constant watching of the progress of the battle and even anticipation of the enemy's movements in order to place the cavalry in readiness to grasp the fleeting moment before too late, consequently the cavalry must often wait for hours even under fire; but of course this has its limits, and after a certain percentage of losses the cavalry must retire out of range, and thus give up temporarily any opportunities for attack that may possibly arise.

The true action of cavalry in battle in former times was shock action, its fire action being quite subordinate and employed mainly on the defensive. Under present conditions the precise sphere of activity for the arm in battle is a subject of debate. Positions seized by an advancing cavalry may sometimes be held by its

means until the infantry comes up, or it may be used to check the advance of the enemy; occasionally it may serve to support infantry. As a rule fire action of cavalry is delivered dismounted, but mounted fire action, although rare, has been used with advantage in covering a retreat when the pursuit was very active. The formation of cavalry used in the attack is the line, composed of two ranks in Europe. At other times the cavalry is generally kept in columns. The line allows of the simultaneous use of the greatest number of weapons, but because of its unwieldiness the squadron front is not exceeded for any formations other than the attack. Columns serve to assemble the troops in a narrow space and render movement up to the moment of attack easy; they must be open to facilitate forming line, with comparatively narrow front and full distances.

In the attack of cavalry against cavalry, victory can be gained only by the rapid assault of closed lines. In the advance of two opposed lines towards each other the respective lines will necessarily be more or less broken, the closed portions of the line still remaining on either side will penetrate the open places, both fronts will thus be broken through, and a hand-to-hand conflict begins. The extent to which either side retains closed lines up to the last will be of great effect on the result, hence the necessity of keeping closed and advancing with determination. The enemy should be kept uncertain as to the direction of the proposed attack as long as possible, so that he cannot prepare to meet the attack on his flank or rear, where it is usually directed. The principles applying to the subdivision of the forces are the same as for infantry. Enough men must be put into action at the beginning to insure success, and the first contact should decide the affair, consequently the forces directed against the flanks must be so directed from the beginning, and therefore must have an entirely different base from those directed against the front. In the front it will hardly be possible to put more men than the enemy has, and overlapping flanks will charge against nothing. More than necessary for decisive action should not be put in at first, because a reserve will be necessary to meet other approaching troops. However, if all the troops are needed for the first effect there can be no reserve, but one should be formed as soon as possible out of the reassembled squadrons. After the attack the action gradually changes into flight on one side and pursuit on the other, and the latter should be kept up till new infantry or artillery stops it, or the horses are exhausted.

In the attack of cavalry against infantry victory can result only when the attack is so sudden that the infantry has no time to fire at all, or when the latter is badly demoralized by previous losses. Cavalry against artillery has a better chance for success, because a firing artillery line cannot protect itself towards the flanks, and in the early part of an engagement such unprotected lines will often be found. Fighting on foot enables cavalry to act for a time independently of the other arms, especially when it is supported by horse artillery, and is the only means by which cavalry can continue its advance through defiles, woods, or villages occupied by weak forces of the enemy. The action of dismounted cavalry is limited in general to holding particular points, such as de-

files or villages, until the arrival of stronger forces. There are, however, instances where cavalry on account of their extreme mobility can be used advantageously in foot fighting, and modern tacticians are paying increased attention to this point. Such cavalry, however, must be distinguished from mere mounted infantry as they have a far wider tactical use.

The principal duty of the horse artillery attached to the cavalry is to support the latter, since it can clear out the enemy from positions which a cavalry force would have hard work to take. In the attack of cavalry against cavalry horse artillery cannot always find application, but it can aid when its cavalry is deploying from a defile. While the opposed cavalries are still manœuvring the artillery takes the enemy's cavalry as its target. Unless the fire of the artillery supporting the cavalry is masked by the latter, or it is desired to aid the deployment of the cavalry, no attention is paid to the enemy's artillery. Artillery duels to prepare the action would be absurd. There will probably be no time for any change of position until after the cavalry attack is decided, when the artillery takes part in the pursuit. In case of defeat it will not have time to take up a new position, but must remain firing in its previous position.

These are in outline the principles involved in cavalry tactics, though they are constantly undergoing modifications and the discussion of the true sphere and use of cavalry is a favorite topic for military authorities. The solution reached in the United States is freely to use cavalry dismounted if circumstances call for this mode of fighting: in other words, no brief is held in favor of mounted action to the exclusion of dismounted. It is believed that this is the correct view of the proper use of cavalry and that foreign armies are slowly accepting it.

#### TACTICS OF FIELD ARTILLERY

The artillery is the arm of destruction, and, on account of its great moral effect and the fact that it can reach troops in every part of the field, in all kinds of ground, and behind all artificial field cover, it is essentially the arm for preparing for the attack, demoralizing the enemy, and facilitating the work of the other arms. The use of artillery in masses is the great feature of a modern battle, and this use results from the long range of the guns, which enables them to do in one position that which formerly required a number. Its mass action begins the battle, prepares it, supports the action of the other arms, and ends it, and as an arm of pursuit artillery ranks with cavalry. The disadvantages of artillery are that it is tied for a considerable period to a particular position, and cannot act alone, consequently it is always an auxiliary arm. Moreover, it is cumbersome in its movement and defenseless when moving. It is also expensive and difficult to train. Leaving out of consideration the artillery of the sea-coast and that used in the attack and defense of land fortifications, which have tactics of their own, treated elsewhere (see COAST DEFENSE and FORTIFICATIONS, ATTACK AND DEFENSE OF), the artillery taken along by the field army may be divided into light artillery and heavy artillery, the former comprising field, horse, and mountain batteries, the latter guns of position. The field batteries include howitzer and mortar batteries for curved or high-angle fire. The

formations of the artillery of practical use in the field are simply a formation for going into battery, and the formation in battery, ready for firing. Beyond the range of firearms the artillery can move in column of platoons, but within that zone it appears only in the open order (in line at full intervals) or in column of sections. Artillery in action always stands in the open order (in battery), and this formation in open order is also the best for advancing into position, where it can be used, but the column of sections will be more generally applicable in coming into position.

The greater range of artillery naturally makes it the arm to open the battle; the desire to rapidly overpower the enemy's artillery, in order that it may take under fire the point selected for attack by the infantry, or, on the defensive, the enemy's infantry during the attack (the real duty of the artillery), as naturally leads to the accumulation of the artillery in masses. The support of the infantry attack is the true purpose and the real duty of the artillery, and everything else is only a means to this end. Consequently, the object which the commander in chief has in view determines the time, place, and strength in which the artillery is first placed in position, and he also must give the orders therefor. The artillery should, of course, endeavor to utilize its long range, and if possible come into position beyond the range of the enemy's infantry fire. It should mask itself from sight on all occasions when the tactical situation or the configuration of the ground permits, since an unmasked battery invites annihilation by the enemy's artillery; but it must not hesitate to take up positions in the open when that is the only means of efficaciously assisting the infantry. It is the duty of the neighboring troops of other arms to protect the artillery against infantry fire. This does not, however, relieve the artillery from the duty of reconnoitering the ground, especially on the flanks, and artillery scouts or patrols have become a necessity on the battlefield. The artillery, once in position, remains there, the losses being made good from the reserve, the ammunition train, and finally the drivers, while ammunition when exhausted can only be awaited. The battery is never relieved, but constantly strengthened and supported from the rear. Before occupying a position the ground must be carefully reconnoitred, and in selecting positions the principal condition is effective action, with concealment if possible. Indirect fire is the rule to-day: this requires that the observers shall be able to see the target, unless the fire is directed by aeroplane observation. This direction by aircraft is becoming more and more the standard. (See MILITARY AERONAUTICS.) As to the distance from the enemy, no rule can be laid down; aircraft observation of hits makes longer ranges possible than were formerly contemplated. Other things equal, fire may be opened at any range within the power of the piece, subject to the possibilities of observation. Effect is more important than cover; consequently, if artillery finds that its fire from a good covered position is not effective, it must enter the danger zone. The great masses accumulated on battlefields to-day greatly limit the choice of position, and in most cases the problem will be less the selection of a position than making the best use of a given position.

The brigade commander rides over the ground,

considers the available space, and with due regard to the targets to be taken under fire, decides what front will be occupied. The regimental and battalion commanders are then given their orders, and the latter indicate to the batteries their respective positions. The batteries then enter their position, keeping the roads as long as possible, and after that utilizing cover when practicable. In large masses it may be necessary to take up first a preparatory position under cover, so that, moved to the front, the batteries may open fire simultaneously, but this is rarely practicable. Brigade and regimental commanders merely indicate the target in general, while battalion commanders designate the special target for each battery and also decide on a change of targets; the ranging, selection of kind of firing, and the actual firing are left to the battery commanders. Changes of position are, in general, ordered only by the commander in chief, but in special cases the artillery must act on its own responsibility. In large masses this change of position takes place by echelons, portions of the line remaining in position and continuing the fire while others advance to the new position.

The attack of the infantry must be supported by the artillery in such wise that the former may overcome the enemy's infantry, consequently the artillery of the attack should be superior to the enemy's from the first. This does not mean necessarily in numbers, because a smaller force by greater rapidity or movement into position and subsequent ranging may gain the upper hand of a large force. If a weaker artillery fears being overpowered it can await in a preparatory position the arrival of reinforcements, but this will not always be possible, because circumstances may demand its action at once. In this case the artillery endeavors to make best use of the ground. In the attack on a prepared defensive front the entire artillery must be in position before opening fire. By superiority of fire is not meant complete silencing of the enemy's artillery, but such an effect that, after the artillery duel, which first takes place, the enemy's artillery is no longer able to direct a destructive fire on the attacking infantry. As soon as the attacking infantry approaches too near the enemy the artillery must direct its fire on the ground beyond the objective, to prevent the advance of subdivisions from the rear. This sort of attack received a notable development in the European War; the *tir de barrage*, or curtain fire, has simply placed a continuous sheet of projectiles between the attacking infantry, and any hostile troops that might otherwise have come up.

The principal duty of the artillery of the defense is to take the attacking infantry, even though it may have overcome by its fire the infantry of the defense, under such a hail of shrapnel as to cause its attack to break down. But in the beginning it will have to take up the artillery duel, and here it has the advantage of selecting and strengthening its positions. It will not do, however, to occupy its positions at the beginning, because if it should be forced to change it will lose all its advantages. Consequently, it takes up at first a preparatory position, until the direction of the attack becomes known, and this has the additional advantage of preventing the attacker from getting an insight into the defender's plans before the battle opens. The artillery of the defense, however,

cannot devote all its attention to the attacker's artillery. Wherever the infantry of the attacker gains a strong foothold it must be taken under fire. As soon as the attacking infantry prepares for the final assault the entire situation changes, and the defender's artillery takes up its rôle. The main effort is directed against the enemy's infantry, and his artillery is only kept occupied by a few guns. During the artillery duel the guns of the defense were kept under cover; now they must come out for their work. If the artillery of the defense is overpowered it may retire to be placed in position again during the infantry assault, but this will rarely be possible or effective. It is better to keep it in position, the men lying down for better protection, entering into action again at the decisive moment. Should the enemy's attack be successful, the batteries of the defense remain in position firing to the last, for the loss of the guns is no longer a disgrace on the battlefield, provided the situation demands it.

Every army takes into the field batteries of position, heavy batteries, for breaking down obstacles which the ordinary field artillery cannot deal with. These must combine great power with a mobility sufficient to enable them to keep up with the troops. Since they are necessarily some distance behind the other troops on the road, the arrival of these batteries must be awaited. They are used very much like the field batteries, but in the selection of the positions there will usually be more freedom, and their duties and changes of position are ordered only by the commander in chief. The employment of artillery of large calibre by armies in the field is one of the features of the Great War.

#### TACTICS OF THE THREE ARMS COMBINED

For most efficient action all three arms are combined, although under certain circumstances and in small bodies infantry and cavalry can act alone, and under others only two of the arms are combined, as infantry and cavalry, infantry and artillery, and cavalry and artillery.

The addition of artillery to the larger bodies of cavalry confers on the latter the possibility of preparing its attack by artillery fire and strengthening its line when fighting on foot; but the absence of infantry prevents it from fighting an infantry enemy in difficult ground, or in villages, woods, or intrenchments. It is therefore used mainly in reconnaissance and pursuit. The addition of artillery to infantry greatly increases the offensive and defensive power of the latter; but absence of cavalry prevents this combination from obtaining timely information of the enemy or properly screening the forces from his view. The addition of cavalry to infantry confers on the latter security on the march and in battle; but for reconnaissance or pursuit the presence of the infantry interferes with the mobility of the combination, and for battle it is weak in offense or defense, on account of the absence of artillery.

The combination of the three arms is, therefore, the only complete one for the battlefield. For the influence of air craft on tactics, see MILITARY AERONAUTICS.

The subject of organization is closely associated with tactics. Therefore, the reader should consult the article ARMY ORGANIZATION and the articles ARMIES; ARTILLERY; CAVALRY; INFANTRY; INFANTRY, MOUNTED; STAFF; ADVANCE GUARD; OUTPOST; RECONNAISSANCE; and BAT-

TLE. STRATEGY naturally must have its relation to tactics and should be read in this connection. The various arms and materials of war mentioned will be found treated either under such collective titles as ORDNANCE and SMALL ARMS, or under their own heads.

**TACTICS, NAVAL.** The science of arranging combinations, groupings, movements, and methods of handling of ships and other naval weapons, and the art of carrying these plans into effect. Roughly speaking, tactics may be said to solve the question how a certain operation may be performed; strategy to furnish the reason why it is likely to be desirable. They are necessarily mutually dependent; tactics only provides for effecting conditions found desirable by strategy; and strategy is confined to operations which are tactically practicable. In its broad sense naval tactics includes the manipulation of all naval weapons—the movements of a ship or of a fleet, the methods of mounting and placing guns and of handling them, the placing of torpedo tubes and their handling, etc. In a narrower and more usual sense it is understood to mean the handling of a ship and her weapons or of several ships, leaving the tactics of the gun per se to be included in gunnery, and those of the torpedo to be studied under torpedo tactics.

Of the abstract principles of strategy the most important is to oppose to the enemy at the point of contact a superior force. This may mean more powerful ships, numerical superiority, or a better arrangement for attack and receiving attack. The first point must be secured by superior design; the vessel's guns

FIG. 1. FLEET IN LINE, NATURAL ORDER.

Showing numbers of section (S), division (D), and squadron (Sq.).

must be more powerful, better mounted, better protected, or she must carry more of them; or her protection or speed must be superior. Nu-

merical superiority where the opposing ships are equal in number and supposedly equal in power may be attained only by good manœuvring and is likely to be only temporary; but a clever tactician and strategist would be likely

FIG. 2. FLEET IN COLUMN, NATURAL ORDER.

Showing numbers of sections (S), divisions (D), and squadrons (Sq.).

ships to be made and kept with reasonable precision. And the development of signaling has added to the facility of effecting these combinations, though the most experienced naval officers believe that after a fleet action has begun the changes of formation should be simple and few in number.

There are three principal formations, line (Fig. 1), column (Fig. 2), and echelon (Fig. 3). In England line is frequently called "line abreast" and column styled "line ahead."

In Figs. 1 and 2 a fleet of 16 ships is shown divided into two squadrons of eight ships each. If the fleet consisted of 12 ships it might be divided into three squadrons of four ships each, or two squadrons of six. In the various navies of the world the subdivisions of a fleet are different. Some have units of two, others of three. In the United States navy a fleet consists of two or more squadrons: a squadron, of two to eight ships;

to reproduce the inequality whenever opportunity offered. The best disposition of the fleet for attacking and receiving attack must depend upon many circumstances; advantage should be taken of the strong points of your own vessels and the weaknesses of the enemy's. For instance, the better protected ships should seek close action, the others avoid it; ships having heavy bow and stern fire should seek action compelling bow and stern fighting if the enemy is particularly weak in bow and stern guns but relatively strong in broadside fire, etc.

The battle tactics of to-day resemble more nearly those of the galley period than those of the epoch of sail, because steam, like manual power, enables any sort of combination of

a division is half of a squadron which consists of more than five ships; a section is a pair of ships forming part of a division or squadron. Vessels, sections, divisions, and squadrons are numbered from van to rear when

FIG. 4. SQUADRON IN INDENTED LINE, NATURAL ORDER.

in column and from right to left when in line. When vessel No. 1 is leading in column or is on the right when in line the fleet is said to be in natural order; if vessel No. 16 is leading or on the right the fleet is said to be in inverted order. Vessels not intended for the

FIG. 5. SQUADRON IN INDENTED COLUMN, INVERTED ORDER.

line of battle are separately formed and manœuvred and constitute the reserve and auxiliary squadrons according to their character or the circumstances of the case. Vessels which have a distinct fighting value but are not fast enough or powerful enough to join the fighting line would form the reserve; supply ships, colliers, repair ships, etc., would form the auxiliary squadron. The following terms are used:

*About.* A change of course of 180 degrees. *Advance.* Distance gained to the front in turning. *Alignment.* The direction of the line. *Arc of train or fire.* The angle through which guns may be trained or fired. *Column.* A formation in which vessels are in a line which

is in the direction in which they are steering. *Double column* is a similar formation except that there are two parallel lines. In *indented column* the even-numbered ships are moved slightly to one side instead of being directly in rear of the odd-numbered ones. *Distance.* The linear distance (in yards) between the centres or foremasts of ships when in ordinary

FIG. 6. FLEET IN LINE OF DIVISION COLUMNS, NATURAL ORDER.

formation. This is usually 500 yards for a battleship or battle cruiser squadron or fleet. *Half distance* is half this. *Double distance* is twice distance. *Echelon.* A formation in which the line of bearing of the ships makes an angle of about 45 degrees with the direction in which they are steering, as in Fig. 3. *Evolution.* The combination of movements by which a fleet is changed from one formation to another. *Flank.* The sea to the right of the fleet is called the right flank; that to the left is called the left flank. *Formation.* The particular arrangement of the fleet. Simple formations are column,

line, echelon, etc. Compound formations are double column, line of division columns, etc. *Front*. The direction in which the fleet is steaming except when obliquing. The battle front is

FIG. 7. SQUADRON, COLUMN RIGHT.

the direction of the enemy. *Guide*. The ship designated as the one upon which the formation is arranged for alignment and distance. *Interval*. The distance between divisions or squadrons when in compound formation. *Line*. A

FIG. 8. SQUADRON, COLUMN RIGHT, TWELVE POINTS.

formation in which the line of bearing of the ships is at right angles to the direction in which they are steaming. *Line of bearing*. An imaginary line passing through the centres or foremasts of ships when in a particular formation. In compound formations each part has its own

FIG. 9. VESSELS, RIGHT ABOUT (EXECUTED FROM LINE).

line of bearing. *Movement*. One of the component parts of an evolution. A movement is simultaneous when all ships execute it together, and successive when executed by each ship or group of ships in turn. *Oblique*. A change of course of less than 90 degrees. The ordinary oblique is three or four points. *Order*. The arrangement of the fleet (see preceding pages).

*Point*. One thirty-second of a circle or  $11\frac{1}{4}$  degrees. *Rear*. The direction opposite to the front. *Speed*. Standard or battle speed is that designated for battle or manœuvres. Full speed is a designated speed greater than standard; half speed is a designated speed less than standard; and slow speed is still less. *Tactical diameter*. The perpendicular distance between the course at the beginning of a turn of 180 degrees and the course after the completion of the turn. *Transfer*. Distance gained to the right or left (i.e., towards the flank) in turning. *Turn*. A turn is a change of course of 90 degrees; a half turn is a change of 45 degrees. *Van*. The leading unit of a formation. *Wheel*. A movement in line in which the vessels preserve their relative positions but the line of bearing is revolved.

In performing evolutions there are two principal methods, by rectangular movements and by direct or oblique movements. Certain evolutions also admit of move-

FIG. 10. FORM COLUMN, RIGHT VESSEL FORWARD, OTHER VESSELS RIGHT OBLIQUE.

ment by isodrome and others by conversion or wheel. The ease of movement attainable with bodies of men is not possible with ships. There can be no turning with fixed pivots, because

FIG. 11. VESSELS, RIGHT TURN.

The manœuvre changes column to line in this instance.

ships must continue in motion or they cannot be kept under control; nor are sudden halts possible, for a heavy ship moving at high speed

cannot be stopped in a less distance than several times her length. These and other considera-

speeds in all ships. The movement by isodrome has no advantage over the ordinary

tions have led to the general acceptance of certain rules.

FIG. 13. SQUADRON, RIGHT WHEEL, FOUR POINTS.  
Executed similarly for any given number of points.

First. Movements during battle should be as simple as possible.

Second. Changes in speed, particularly during evolutions, should be avoided as far as possible.

Third. Evolutions should be performed by the method which requires the least time and the least space.

Fourth. Ships of like characteristics should be separately grouped as far as possible; this is particularly true as regards speed and hardly less so as regards power and arrangement of battery and armor.

Fifth. When approaching the enemy and until in position to deliver attack the fleet must be kept concentrated and in condition to assume any desired formation.

These rules preclude the use of oblique movements, except under special circumstances, as they require more time and

See ADVANCE GUARD.

**TACUBAYA**, tă'koo-bă'yă. A Mexican town in the Federal District, the head of the prefecture of that name, three miles southwest of the City of Mexico (Map: Mexico, C 9). It is a fashionable suburb and is famous for its gaming establishments and handsome villas. It is pleasantly situated, partly on a plain and partly on a hillside, which is crowned by an ancient episcopal palace, now used as one of the national observatories. Pop., 1910, 37,552.

**TACUL'LI** (Carriers), or **TAKULLI**. A tribe of Athapascan stock (q.v.) residing about Stuart and McLeod lakes, on the headwaters of the Peace and Fraser rivers, in Central British Columbia. Their social organization was based on the clan system. Their canoes were neatly made from birch bark; they hunted during the winter season on snowshoes; and their women spun yarn from the hair of the mountain goat and also made a coarse pottery. They are all now Christianized through the efforts of French Catholic missionaries, who devised for their language a syllabic alphabet in which nearly all have learned to read and write, although they have no schools. The Taculli are gathered on small reservations, and numbered in 1916 about 800 individuals.

The Déné syllabary, as it is called, is the invention of the Rev. Adrien Morice, who began his mission work among the Athapascan tribes of British Columbia in 1880. It consists of 30 characters, which by inversion of position and the use of accompanying dots or dashes can be made to indicate nearly 200 distinct syllables or sounds common to the Taculli, Chilcôtin, and other neighboring cognate languages. Its printed literature consists of textbooks, religious works, and the *Carrier Review*, a monthly journal formerly published by Father Morice at Stuart Lake. Consult Adrien Morice, in *Transactions of the Canadian Institute* (Toronto, 1893).

**TADEMA**, tă'dê-mă, ALMA-. See ALMA-TADEMA.

**TAD'MOR**. Another name for Palmyra (q.v.).

**TADPOLE** (ME. *tadpolle*, *taddepol*, from *tadde*, *tade*; toad, AS. *tādige*, *tādie*, toad + *polle*, head, poll). The larval form of anurous amphibians. For its metamorphosis see TOAD.

**TAEL**, tăl (Portug. *tael*, from Malay *tail*, *tahil*, weight, tael, from Hind. *tōla*, weight, from Skt. *tulā*, balance). The name commonly given to the Chinese *liang*, a money of account in China, and worth from 0.724 to 0.806 of an American dollar, but varying in value in different parts of the Empire.

**TAENARUM**. See CAPE MATAPAN.

**TÆ'NIA**. An animal parasite developed in

the intestines of man and some animals. See TAPEWORM.

In architecture, a narrow projecting fillet or square molding along the upper edge of the architrave in a classic or neoclassic entablature. See ENTABLATURE and ORDERS OF ARCHITECTURE.

**TÆ'NIOP'TERIS** (Neo-Lat., from Gk. *rawia*, *tainia*, band, ribbon + *ptēpis*, *ptēris*, fern). A genus of fossil ferns found in rocks of late Paleozoic and Triassic age. They have long leathery fronds of linguete form with entire margins, a strong central rib, and numerous closely parallel veins that run at right angles from the midrib to the margins. The fruiting frond is not known. See FERN.

**TAENSA**, tă-ēn'să, or **TENSA**. An historic American Indian tribe living, when first known to the French, about the year 1700, in seven villages between the Tensas River and the Mississippi, in the present Tensas Parish of Louisiana, about 20 miles from Natchez. Like the neighboring Natchez (q.v.), with whom they seem to have been closely connected, they were sun-worshippers and kept a sacred fire constantly burning in a temple. A part of the tribe, driven out by the Chickasaw (q.v.), was afterward colonized by the French on the west side of Mobile Bay, in the neighborhood of Mobile, Ala., where the local name still remains. The settlement contained 100 cabins about 1750. At a later period they removed higher up the Alabama River near the site of the present Tensaw. They were probably merged finally into the Choctaw or the Creek Confederacy. Nothing is known positively of their language, the *Grammaire et vocabulaire de la langue Tensa* by Haumonte, published in Paris in 1882, having been proved to be a transparent fraud. According to contemporary French testimony, however, the language was cognate with that of the Natchez. Consult J. R. Swanton, *Indian Tribes of the Lower Mississippi Valley and Adjacent Coast of the Gulf of Mexico* (Washington, 1911).

**TAFELBERG**, tă'fel-bērg. See TABLE MOUNTAIN.

**TAFFANEL**, JACQUES PIERRE. See LA JONQUIÈRE, MARQUIS DE.

**TAFFETA** (OF., Fr. *taffetas*, from Pers. *tāftah*, *taffeta*, woven, p.p. of *tāftan*, to weave). A term of somewhat general application in silk manufacture. It was formerly applied to all plain silks simply woven by regular alternations of the warp and filling (see WEAVING), and is by some writers supposed to be the first kind of silk weaving known even to the Chinese, from whom it came to us. Modifications have, however, been introduced, by varying the quality of the warp and filling, and by the substitution of various colors for the single one of the original taffeta. It has therefore become a sort of generic term for plain silk, or silk woven in lines so fine as to appear plain woven. Taffeta has the same appearance on both sides. See Plate of TEXTILE PRINTING.

**TAFFRAIL LOG**. See LOG.

**TAFFY**. See NATIONAL NICKNAMES.

**TAF'ILET'**. A large oasis in the northwestern part of the Sahara, belonging to Morocco, and situated at the southern base of the Atlas Range, 200 miles south of Fez. Area, about 500 square miles. The chief product is dates, but the oasis is mainly important as one of the principal trading stations between Morocco and the Sudan. The oasis includes about 150 towns and

villages, the largest and the most important commercial centre being Abuam. Population of the oasis, about 120,000.

**TAFT, CHARLES PHELPS** (1843- ). An American newspaper owner and editor, half brother of Henry W. Taft and William H. Taft. He was born at Cincinnati, Ohio, graduated from Yale in 1864, and studied at Heidelberg, Berlin, and Paris. Admitted to the bar in 1866, he practiced law from 1869 to 1879, when he purchased the Cincinnati *Times*. This paper he consolidated with the *Star* in 1880 as the *Times-Star*, of which he was thereafter editor. He served as a member of the Ohio House of Representatives in 1871, and of the 54th Congress (1895-97). From 1898 to 1908 he was president of the Cincinnati Board of Sinking Fund Trustees. In the latter year he was a delegate to the Republican National Convention.

**TAFT, HENRY WATERS** (1859- ). An American lawyer, brother of William H. Taft and half-brother of Charles P. Taft. Born at Cincinnati, Ohio, he was educated at Yale (A.B., 1880), and studied at the Cincinnati and Columbia law schools. After 1882 he practiced law in New York City. Until his resignation in 1907 he was special assistant to the United States Attorney-General in the prosecution of the Tobacco Trust. He served as trustee of the College of the City of New York in 1903-05, and of the New York Public Library after 1908, and became chairman of the council of the University Settlement.

**TAFT, LORADO** (1860- ). An American sculptor. He was born at Elmwood, Ill., was educated at the University of Illinois, and studied art at the Beaux-Arts, Paris, under Dumont. Returning to America, he settled in Chicago, becoming in 1886 an instructor at the Art Institute. Here he exercised considerable influence upon western artists. He became widely known as a public lecturer, and in 1909 he was appointed professorial lecturer in the University of Chicago. His sculpture is well composed with a happy combination of ideal and realistic tendencies, but is somewhat lacking in strength. The most important works include the Washington Monument, Seattle; a military group at Jackson, Mich.; various fountains, such as the "Columbus Memorial Fountain," Washington; and ideal subjects, as "The Blind," inspired by Maeterlinck's drama (1909), and "Solitude of the Soul" (Art Institute, Chicago). Taft undertook to carry out a grand scheme of sculptural decoration for Chicago, made possible by the bequest of Benjamin F. Ferguson in 1905. One group, the "Spirit of the Lakes," was finished in 1913, and another, the colossal "Fountain of Time," was nearing completion in 1916. Taft was elected to the National Academy (1911), the National Sculpture Society, and the National Institute of Arts and Letters. He published a *History of American Sculpture* (1903), the best work on the subject treated.

**TAFT, WILLIAM HOWARD** (1857- ). The twenty-seventh President of the United States, born Sept. 15, 1857, in Cincinnati, Ohio. He graduated from Yale in 1878, second in a class of 121, and from the Cincinnati Law School in 1880, dividing with another the prize for scholarship. Instead of entering practice immediately he became law reporter for the Cincinnati *Times* (Charles P. Taft's paper) and later for the *Commercial*. In 1881-82 he was assistant prosecutor of Hamilton County, in 1882-83 was a col-

lector of internal revenue. From 1887 to 1890 he served as a judge of the Superior Court of Ohio, and had been elected to succeed himself when he was appointed United States Solicitor-General in 1890 by President Harrison. His able argument and opinions in the Bering Sea Cases (*In re Cooper*, 138 U. S., 404; 143 U. S., 472; see *BERING SEA CONTROVERSY*) and the tariff cases brought him wide notice and a national reputation. In 1892 he was appointed a judge of the newly created Circuit Court of Appeals (sixth circuit), serving until 1900. He had occasion to hand down certain decisions relative to railroads, corporations, and organized labor which were of far-reaching consequence in the development of the law of injunctions (q.v.). In the case of *Moore v. Bricklayers' Union*, he declared a secondary boycott illegal. Although holding that labor has the legal right to organize in unions, he declared that unions must refrain from acts injurious to society. Thus when *Debs* (q.v.), in 1894, endeavored to tie up traffic, Taft granted an injunction against his agent, F. W. Phelan. From 1896 to 1900 Taft was dean and professor of law at the University of Cincinnati.

In 1900 he resigned his judgeship to become the chairman of the commission appointed by President McKinley to institute civil government in the Philippine Islands (q.v.), although he had been opposed to annexation. In his four years' residence in the Islands he not only fulfilled the objects of the appointment, but attained a wide and well-founded popularity as an able colonial administrator. Order having been gradually effected, he began to introduce the rudimentary forms of civil government. The government was organized, good roads were built, post offices established, schools and American teachers introduced, banks founded, and civic improvements made. Sanitation removed much of the danger of epidemics of contagious diseases. In 1902 Mr. Taft visited Rome to negotiate with Pope Leo XIII terms for the purchase of the friars' lands. Having succeeded, he induced Congress to appropriate \$7,230,000 for this purchase, and then sold the lands to the tenants and inhabitants on easy terms. He regarded the Filipinos as unprepared to govern themselves and urged that they be educated for that purpose before the United States should contemplate giving them independence. He advocated free trade and the development of sympathy between them and Americans. He won the trust of a large portion of the natives, who asked him to remain with them, in 1903, when he was offered a place on the Supreme Court bench by President Roosevelt. In 1904, however, he succeeded Elihu Root as Secretary of War in Roosevelt's Cabinet, and soon was regarded as the friend and spokesman of the administration. He represented it in many important trips in the United States and in foreign states. In 1906 he was temporarily the civil Governor of Cuba (q.v.) after the intervention of the United States in that year. In 1907 he visited the Panama Canal zone in order to familiarize himself with the problems and conditions there. In 1907, also, he visited the Philippines to be present at the opening of the Legislative Assembly. He then went to Japan to confer with that government relative to the problem of the Japanese in the United States and succeeded in arranging matters satisfactorily for the time. He proceeded to China, where he undertook important nego-

tations relative to Chinese boycott of American commodities, and then to Russia.

Before 1908 President Roosevelt had let it be known that he favored Taft as his successor and in that year actively supported the latter's candidacy. Because of the President's powerful influence and his own popularity, Taft easily secured the Republican nomination for the presidency. He was overwhelmingly elected over Bryan, the Democratic candidate, securing 321 electoral votes against 162. Four years later, in 1912, he acknowledged his indebtedness to Roosevelt, and it was well known that he had indorsed the Roosevelt policies.

In his inaugural address and message to Congress, he urged a revision of the tariff on the basis of affording American business interests protection equal to the difference between the cost of producing manufactured articles at home and abroad, a graduated inheritance tax, a postal savings bank system, a strong navy, and mail subsidies for American ships. He called a special session of Congress in order to secure revision of the tariff law. The result was the enactment of the Payne-Aldrich Tariff Act, which he signed and in 1910 defended at Winona. The widening of the breach between the "stand-patters" and the insurgents within the party caused many to think Taft a failure as a party leader. The tariff act was unpopular, and the Ballinger-Pinchot controversy (see CONSERVATION; BALLINGER, R. A.; PINCHOT, GIFFORD) and certain other scandals connected with the Department of Agriculture brought the administration into disfavor and encouraged the Progressive movement. The result appeared in the overthrow of "Cannonism" and the defeat of the party in the Congressional elections of 1910. The President's defense of Ballinger and of the tariff act together with his coöperation with the conservatives in Congress caused him to be regarded as a reactionary. His championship of Canadian reciprocity in 1910 and the adoption of it by aid of Democratic votes was nullified in the public mind by its failure in Canada and by his vetoes of tariff reform bills which were passed by Congress in 1911. This action was regarded as a failure to conform to platform pledges. In 1910-11 he made a notable effort to secure the ratification of peace and arbitration treaties which had been negotiated with Great Britain and France, and subsequently he was known as one of the most prominent advocates of world peace and arbitration.

By 1912 Taft and Roosevelt had broken relations. Both announced their candidacy for the Republican nomination and waged a bitter campaign. (See ROOSEVELT; PROGRESSIVE PARTY.) Taft secured the nomination on the first ballot, but, in competition with Roosevelt, now head of the Progressive party ticket, and Woodrow Wilson, Democrat, he was defeated in the election by Wilson, receiving only 8 electoral votes. During the last month of the administration, there was a revival of his personal popularity and of confidence in his administrative ability. On retirement, in 1913, he became Kent professor of law at Yale University, and in the same year was elected president of the American Bar Association. In 1915 he criticized severely the Wilson administration's attitude towards the Philippine Islands. In 1916 he became chairman of the Central Committee of the American Red Cross. Mr. Taft wrote: *Four Aspects of Civic Duty* (1906); *Present-*

*Day Problems* (1908); *Political Issues and Outlooks* (1909); *The Anti-Trust Act and the Supreme Court* (1914); *The United States and Peace* (1914); *Popular Government* (1915); *Ethics in Service* (1915); *The Presidency: Its Duties, Opportunities, and Limitations* (1916). Consult Mrs. W. H. Taft, *Recollections of Full Years* (New York, 1914); J. G. Wilson (ed.), *Presidents of the United States, 1789-1914*, vol. iv (ib., 1914). See UNITED STATES, *History*.

**TAGABILL**, tà-gà-bé'lé. A Malay people said to inhabit a part of the country bordering on Lake Buluan in southern Mindanao. See PHILIPPINE ISLANDS.

**TAGAKAULO**, tà-gà-kà-ō'lō (or KAGAN or KALAGAN). A turbulent Malay tribe inhabiting the lower slopes of the mountain ranges west of Davao Gulf, in Mindanao. They practice a little agriculture, but the men are essentially hunters and warriors, who for many years have carried on a lucrative slave trade with the coast Moro. Consult F. C. Cole, *Wild Tribes of Davao District* (Field Museum publication, 1913). See PHILIPPINE ISLANDS.

**TAGALOG**, tà-gü'lōg (TAGALA, TAGAL). A people inhabiting central Luzon, the district surrounding Manila Bay, and parts of neighboring islands, particularly the coasts of Mindoro. At the time of the Spanish conquest they had acquired some culture, were in possession of a native alphabet, and were carrying on considerable trade with the Chinese and Moro. Upon the advent of the Spaniards, Manila became the most important city of the archipelago, and many advantages, denied to the natives of other tribes, were secured by them. Their country received by far the greater number of emigrants, intermarriage with whom has resulted in a large population of mixed blood. Numerically the Tagalog rank second among the Philippine tribes, but because of their greater advancement they are to-day the dominant people of the Islands. See PHILIPPINE ISLANDS.

**TAGANROG**, tīg'an-rōg'. A district town and seaport in the Province of the Don Cossacks, Russia, on the north coast of the Sea of Azov, 18 miles northwest of the mouth of the Don (Map: Russia, E 5). The harbor has now become very shallow and the trade of the town is decreasing. The principal export is grain. The manufacturing industries are well developed and the principal products are flour and tobacco. The town contains the famous Chekhov Museum, founded in honor of the great Russian writer, who was born here in 1860. Pop., 1910, 68,369.

**TAGASASTE**. See CYTISUS.

**TAGBANUA**, tag-bā'nō-ā (Palawan). A pagan people inhabiting a large part of the island of Palawan, and some of the adjacent islands of the Calamian group. They are broken up into several divisions, the members of which differ in looks and culture according to the amount of intercourse they have had with the pygmy tribes, or coast Mohammedans. Those who have had extensive dealings with the latter have borrowed from them their type of dress and many articles used in daily life. The tribe has a syllabic alphabet with which they write their language. Smooth joints of bamboo are used as a substitute for paper, and on them the characters are scratched. Consult M. H. Venturello, "Manners and Customs of the Tagbanua," in Smithsonian Institution, *Miscellaneous Collections*, vol. xlviii, part iv (Washington, 1907). See PHILIPPINE ISLANDS.

**TAGGART, THOMAS** (1856- ). An American politician, born in Ireland. He arrived at Indianapolis, Ind., in 1872 and after a time opened a small hotel. Subsequently he became proprietor of the Grand Hotel at Indianapolis and finally acquired most of the stock of the French Lick Springs Hotel Company. As a Democrat he was elected auditor of Marion Co., Ind., in 1886, an office then reputed to yield a large total in fees. Two years later he was appointed Democratic county chairman and succeeded in carrying the county against Benjamin Harrison, candidate for the presidency. For this feat he was rewarded with the State chairmanship of the party in 1892. Elected mayor of Indianapolis in 1895, he was twice reelected and refused a fourth nomination. As chairman of the Democratic National Committee he conducted the presidential campaign of Alton B. Parker (q.v.) in 1904. Taggart was beaten in his contest for the senatorial nomination by John W. Kern in 1910 and by Benjamin F. Shively in 1914, but upon the latter's death in 1916 he was appointed by his political ally, Governor Ralston, to fill the vacancy. In 1915 Taggart was indicted by a grand jury for alleged election frauds at Indianapolis, but the case was later dropped.

**TAGHKANIC** (tá-kí'nik) **MOUNTAINS.** See TACONIC MOUNTAINS.

**TAGILSK, NIZHNI.** See NIZHNI TAGILSK.

**TAGINÆ.** See GUALDO TADINO.

**TAGLIACOZZO,** tál'yá-kòt'só. A town in the Province of Aquila, Italy, about 50 miles from Rome, near which, on Aug. 23, 1268, Charles of Anjou decisively defeated Conradin of Swabia (q.v.), the last of the Hohenstaufen.

**TAGLIONI,** tá-lyó'né, MARIA (1804-84). An Italian ballet dancer. She was the daughter of Filippo Taglioni (1777-1871) who was ballet master successively at Stockholm, Cassel, Vienna, and Warsaw, and composed many ballets. Maria, who was born at Stockholm, was trained by her father, in one of whose ballets she first appeared at Vienna in 1822. Five years later she made her Paris debut, which was a tremendous success. She became particularly famous for her dancing in *La Sylphide*, the best of her father's ballets, and in *Guillaume Tell*, *Robert le Diable*, and other operas. Throughout Europe Taglioni became a name to conjure with. In 1832 she married Count Gilbert de Voisins. In 1847 she retired from the stage. Later, after she had lost money by speculation, she supported herself by teaching court etiquette in London. Taglioni died at the home of a son in Marseilles.

Her brother PAUL (1808-84) was appointed ballet director of the Royal Theatre, Berlin, in 1869, and as a composer of ballets earned a reputation by *Flick und Flock* and *Fantasia*. His daughter, MARIA (1833-91), also a dancer, was a great favorite at the Royal Theatre in Berlin and later at San Carlo in Naples. In 1866 she married Prince Joseph Windischgrätz.

**TAGORE,** tá-gör', SIR RABINDRANATH (also written THAKURA, RAVINDRANATH) (1860- ). A Hindu poet. Long popular in India, he gained an international reputation and was awarded the Nobel prize in literature for 1913. Born in Calcutta of a distinguished family, at the age of 17 he went to Europe to complete his education. On his return to India he first became known as an educator and philosopher, being the founder of a university in Bengal. To

a magazine conducted by his family he was also a frequent contributor. Tagore's native language was Bengali (q.v.), and his poetry possessed an extraordinary power of appeal to his compatriots—a power which was measurably felt among alien and Western peoples who read the English versions of parts of his work, which he himself had translated in a style of remarkable charm, suppleness, and finish. His verse, which in his early years was sensual and romantic, became with his maturity more spiritual and idealistic. Tagore spent some time in America at Urbana, Ill., and in New York. He was knighted by King George in 1915. There are English versions of his: *The Crescent Moon* (1913), children's poems; *The Gardener* (1913), poems; *Gitanjali* (1913), prose translations of poems; *Sādhanā: the Realization of Life* (1913), a series of essays; *Chitra* (1913), a one-act play; *The King of the Dark Chamber* (1914); *The Post Office* (1914); *Short Stories* (1915). Consult Ernest Rhys, *Rabindranath Tagore* (New York, 1915), and B. K. Roy, *Rabindranath Tagore* (ib., 1915).

**TAGOSATI,** tū'gō-sū'té, or **TOGASASTI,** tō'gā-sūs'té. A shrub (*Cytisus proliferus albus*) of the family Leguminosæ. It is a native of the Madeira and the Canary islands, where it is an important fodder plant and whence it has been introduced into southern Australia. It is well adapted to dry soils and climates, but cannot be depended upon where there is danger of frost.

**TAGUAN,** tū'gwūn (East Indian name). A large Old World flying squirrel (*Pteromys petaurista*). See FLYING PIALANGER.

**TA'GUS** (Sp. *Tajo*, Portug. *Tejo*). The largest river of the Iberian Peninsula. It rises in the Sierra de Albarracin on the west boundary of the Spanish Province of Teruel, 88 miles east of Madrid, and flows in a general west-southwest direction through Spain and Portugal, emptying into the Atlantic Ocean shortly after passing the city of Lisbon (Map: Spain, D 2). Its length is 565 miles. In its upper course it traverses the arid plains of New Castile, but at Toledo it plunges through a wild gorge between high granite cliffs. About 40 miles above Lisbon it divides into two branches, which inclose a low, marshy island, and which reunite in the Mar da Pálha (Straw Sea), an expansion of the river about 18 miles long and 5 miles wide, deep and sheltered, forming one of the best harbors in the world. At Lisbon the river again contracts, and enters the ocean through a narrow and deep channel, which, but for the bar at the mouth, would be accessible for the largest ships. The navigation of the Tagus ends within the Portuguese frontier.

**TAHAR'KA** (?-c.608 B.C.). The name of the third King of Egypt of the twenty-fifth or Ethiopian dynasty, who ruled from c.694-693 to 668-667 B.C. He is the Tirkakah of the Bible, the *Tárkos* or *Tarkós* of Manetho, and the Tarqu of the Assyrian inscriptions. He seems to have been a usurper who seized upon the throne on the death of Shabataka, and strengthened his hold upon it by marrying the widow of King Shabako. In the Old Testament (Isa. xxxvii. 9; 2 Kings xix. 9) he is said to have come to the aid of Hezekiah, King of Judah, when Jerusalem was besieged by Sennacherib. It would seem that no battle took place between the Egyptian and Assyrian forces, but that the latter, before they met, were forced to retreat by a pestilence.

In 670 B.C. Esarhaddon, son of Sennacherib, invaded Egypt, defeated Taharka in several engagements, sacked Memphis, and marched to Thebes, which surrendered to him. Taharka retired to Nubia, but returned the next year and established himself in Memphis. Learning of this, Esarhaddon gathered an army and was proceeding to the relief of his Egyptian vassals when he died on the way. His army continued the march and drove Taharka out of Lower Egypt. Retreating to Thebes, Taharka seized that city and was preparing to renew the contest when he died. Memorials of Taharka are found in many parts of Egypt and Nubia. At Napata (Jebel Barkal) he built a temple whose sanctuary was hewn out of the solid rock of the mountain, and he restored the temples of Thebes, his capital. Consult K. A. Wiedemann, *Ägyptische Geschichte* (Gotha, 1884-88), and W. M. Flinders Petrie, *A History of Egypt*, vol. iii (New York, 1905).

**TAHITI**, tā-hé'té, or **OTAHEITE**. The largest of the Society Islands (q.v.), in lat. 17° 45' S., long. 149° 20' W. (Map: World, Western Hemisphere, L 6). Area, 600 square miles. The island consists of two unequal and nearly circular portions connected by a narrow isthmus. These are the remnants of old volcanoes, and rise in a succession of concentric terraces to the summits, the higher of which has an altitude of 7688 feet. The mountains are, however, very much eroded by numerous streams, which have cut large valleys and deep gorges down the slopes, leaving in many places isolated crags which make the scenery very romantic. The climate is warm, but equable, the temperature ranging from 60° F. to 90° F. The rainfall is abundant, and the whole island is covered with a luxuriant vegetation. The central peaks are surrounded by a low strip of coastland consisting of volcanic detritus, which, mixed with coral sands from the surrounding reefs, makes an extremely fertile soil. Nevertheless agriculture is in a backward state, and only a few square miles of land are under cultivation. The population in 1910 was 11,691. The chief town is Papeete, the capital of the French establishments in the eastern Pacific, with a cathedral, arsenal, hospital, and a population in 1910 of 3617, about one-half of whom were French. For history and political and economic conditions, see **SOCIETY ISLANDS**.

The Tahitians are typical Polynesians. They make bark cloth, produce fire by means of the fire plow, tattoo, use kava as a stimulant, and depend on vegetable products for their food, which in the absence of pottery is baked or roasted. A remarkable institution of the Society Islanders was the *Arcois* (q.v.), a society for the cultivation of poetry, the dance, and the drama combined with the indulgence of the sexual passion. Another noteworthy feature of their culture was the fire walk, in which the natives walked on rocks that had been heated for hours. Consult: Lutteroth, *O-Taïti* (Paris, 1843); Vincendon, *Iles Taïti* (ib., 1844); Buschmann, *Aperçu de la langue des îles Marquises et de la langue taïtienne* (Berlin, 1843); P. Huguenin, *Raiatea la sacrée* (Neuchâtel, 1902).

**TAHITI APPLE**. See **HOG PLUM**.

**TAHITI ARCHIPELAGO**. See **SOCIETY ISLANDS**.

**TAHLEQUAH**, tā'lé-kwá'. A city and the county seat of Cherokee Co., Okla., 36 miles by rail east of Muskogee, on the Illinois River,

and on the St. Louis and San Francisco Railroad (Map: Oklahoma, G 3). It is the seat of the Northeastern State Normal School, and contains the Cherokee Training School and a Carnegie library. The chief industrial establishments are cotton gins, grain elevators, and flour mills. Pop., 1900, 1906, 1910, 2891.

**TAHLTAN**, tál'tan. See **NAHANE**.

**TAHOE**, tā'hō or tál'hō, LAKE. The largest lake in the Sierra Nevada, on the boundary between Nevada and California (Map: California, E 3). It is 22 miles long by about 10 miles broad, and lies at an altitude of 6225 feet. Its greatest depth is over 1600 feet, and its water is remarkably clear. It discharges through the Truckee River into Pyramid Lake, and it has been planned to draw its water through tunnels for irrigation purposes.

**TAHPANHEES**, tā-pān'hēz (Heb. *Tahpan-khēs*), or **TEHAPHINEHES** (Heb. *Tekhaphnekhēs*). A city of northeastern Egypt mentioned in the Bible. It is probably to be identified with the town called by the Greeks Daphnæ, which was situated in the delta about 25 miles southwest of Pelusium. Daphnæ was a military post of some importance in the time of Psammetichus I (q.v.), who fortified it and established in it a garrison of Greek mercenaries. The site, represented by the modern Tel Defennel, was explored by Petrie in 1886. Consult W. M. Flinders Petrie, *Tanis*, part ii (London, 1887), and id., *A History of Egypt*, vol. iii (New York, 1905).

**TAHR**. See **THAR**.

**TAHUTIMES**, tā-hōō'té-mēs. See **THOTHMES**.

**TAIGNANFU**, tig'nān'fōō'. A departmental city of the Province of Shantung, China, situated at the foot of the famous Mount Tai (see **TAI SHAN**), 60 miles south-southeast of Tsinanfu, the capital of the province. The importance of Tainan is due chiefly to the immense numbers of pilgrims who come to visit Mount Tai. Its suburbs on the south and west, however, are large, populous, and prosperous. The most important of the numerous temples of Tainan is the Tai Temple, covering several acres, surrounded by a strong wall and containing many fine old cypresses. Pop., with suburbs, about 80,000.

**TAIKUN**. See **TYCOON**.

**TAILFER**, PATRICK. An American colonist, remembered for the polemic entitled *A True and Historical Narrative of the Colony of Georgia in America from the First Settlement thereof until the Present Period* (1741). Tailfer, a physician who had emigrated to Georgia, disapproved of the administration of the Colony. In 1740 he went to Charleston, S. C., where, with the assistance of Hugh Anderson and David Douglass, he published the work mentioned above. In this he mercilessly attacked Governor Oglethorpe.

**TAILHADE**, tā'yād', LAURENT (1854-1919). A French poet, born at Tarbes and educated at the lycée of Pau. He was early a journalist. His first writing, which shows a Parnassian (see **PARNASSIENS**) influence, was well received by De Banville (q.v.). Tailhade is noted for ballads and satirical verse. His best work is in *Le jardin des rêves* (1880); *Au pays du muflé* (1891); *A travers les grouins* (1899); *Poèmes aristophanesques* (1904); *Poèmes élégiaques* (1907); *Un monde qui finit* (1909); *La forêt* (1910); *Pages choisies* (1912).

**TAILLANDIER**, tā'yān'dyā', RENÉ GASPARD ERNEST, commonly called **SAINT-RENÉ TAILLANDIER** (1817-79). A French writer on

literature and history, born in Paris. He studied law, but turned to literature and philosophy, and in 1840 attracted some attention with his long poem *Béatrice*. In 1841 he studied at Heidelberg, and at the end of that year became a member of the Faculty of Letters at Strassburg. In 1843 he received the doctor's degree at Paris for his *Scot Erigène et la philosophie scholastique*, and then was called to the chair of French literature at Montpellier. From 1863 he was a professor in the Faculty of Letters at Paris, and in 1873 became a member of the Academy. Especially noteworthy are his writings on German literature and philosophy, which began in 1843 in the *Revue des Deux Mondes*. His works include: *Histoire de la jeune Allemagne* (1848); *Études sur la révolution en Allemagne* (1853); *Allemagne et Russie* (1856), a study made timely by the Crimean War; *Histoire et philosophie religieuse* (1860); *Littérature étrangère, écrivains et poètes modernes* (1861); *La Comtesse d'Albany* (1862); *Correspondance entre Goethe et Schiller* (1863); *Corneille et ses contemporains* (1864); *Maurice de Saxe* (1865), a critical biography; *La Serbie au XIX<sup>ème</sup> siècle: Kara-George et Milosch* (1875); *Deux ans de l'histoire d'Allemagne* (1875); and *Le roi Léopold et la reine Victoria* (1878).

**TAILLE**, täl; Fr. pron. ta'y'. In mediæval England and France an arbitrary tax enacted by a seignior from his vassal. In France, specifically it became a royal tax which was originally imposed for the maintenance of the national defense, and which in the course of time came to fall on the lower classes only, exemption from the tax being in fact the great mark of distinction between the privileged and non-privileged classes, the *tailables* and *nontailables*. See FRANCE; SERF.

**TAILLE**, JEAN DE LA. See LA TAILLE, JEAN DE.

**TAILLON**, täl'yôn', SIR LOUIS OLIVIER (1840-1923). A Canadian statesman. He was born at Terrebonne, Province of Quebec, and educated at Masson College. Called to the bar in 1865, he practiced his profession in Montreal and became one of its leaders in the province. He was elected a Conservative member of the Provincial Legislature in 1875 and sat therein until 1896. He was Speaker of the Legislative Assembly (1882-83), Attorney-General (1884-86), Premier (1887: 1893-96), leader of the Opposition (1887-90). In 1896 he was appointed Postmaster-General in the Dominion cabinet of Sir Charles Tupper, but resigned on the latter's defeat the same year. In 1900 he was an unsuccessful candidate for the House of Commons. He was knighted in 1916.

**TAILOR**, ROBERT. An English dramatist, of whose life very little is known. He is remembered for his comedy *The Hog Hath Lost his Pearl*, which was presented in London in 1613 and printed the following year. The play is valuable for its many dramatic allusions, but has little merit. Tailor is supposed to be the author of *Sacred Hymns*, 50 rather meritorious paraphrases from the Psalms.

**TAILOR BIRD**. One of a group of small Oriental thrushes or warblers of the genus *Orthotomus*, which stitch together leaves to sustain their nest. There are many species and allies, but the tailor bird proper is *Orthotomus sutorius*, which is common in India and eastward about gardens. It has a back of olive green, is white beneath, the crown of the head

is chestnut, and in the male two middle tail feathers are greatly elongated. The bill is long, straight, and slender. It is said to make its nest of cotton and other soft materials, drawing one leaf or more, generally two, on each side of the nest, and stitching them together with threads picked up. The process has been witnessed, however, by few competent observers. The fullest account extant is in Hume, *Nests and Eggs of Indian Birds* (2d ed., London, 1890); also consult Douglas Dewar, *Birds of the Plains* (New York, 1908). The birds of a related genus, *Cisticola* (see FANTAIL), "ply the same trade on stems of grass, confining them by stitches above the nest, which is built among them and takes a globular form." See PLATE of PENSILE NESTS OF BIRDS accompanying NIDIFICATION.

**TAILOR'S GOOSE**. See GOOSE, TAILOR'S.

**TAIMYR**, ti-mër'. A large peninsula of northwest Siberia, in the Government of Yeniseisk, extending into the Arctic Ocean and forming the northernmost part of the Asiatic mainland (Map: Asia, L M 1). The peninsula is divided by Taimyr river, lake, and bay into two parts, of which the more easterly is the larger and reaches the parallel of lat. 77° 34' N. This part of the peninsula has many headlands and contains the Byrranga Mountains, which are only about 1000 feet in height. The Taimyr River rises in lat. 73° N., flows through the large Lake Taimyr (about 1000 square miles), and empties into Taimyr Bay at 75° 35'. The flora is poorer than in that part of Greenland which is not covered by the ice cap. The country is only occasionally visited by nomadic Samoyeds and Ostiaks. It was first explored by the Russian traveler Alexander Theodor von Middendorff.

**TAINAN**, ti'nän'. A city of south Formosa, known as Tai-wan fu until 1886, and the capital of the island until 1896 (Map: Japan, D 8). It is on a level plain of considerable extent, 3 miles east of Formosa Channel, with which it is connected by a canal. Its walls have a circuit of about 6 miles and inclose many open spaces, the principal markets being in the western suburbs. The Dutch made it their capital in the seventeenth century. Tainan was a treaty port under Chinese rule; under Japanese control it has the same status. It has three steam sugar mills and one rice mill. Pop., 1913, 53,794, including few foreigners.

**TAINÉ**, tân, HIPOLYTE ADOLPHE (1828-93). A French historian and critic of literature and art, born at Vouziers, April 21, 1828. He went to Paris in 1841, entered the Ecole Normale in 1848, where he showed much independence and restiveness under its philosophic eclecticism. In 1851 he was appointed to the chair of philosophy at the College of Toulon, but he immediately resigned, studied medicine and the sciences, and so brought himself into touch with the spirit of the rising generation, with whom his essays on *La Fontaine*, *Livy*, and *Les philosophes français du XIX<sup>ème</sup> siècle* (1853-56) won immediate recognition, while his *Voyage aux eaux des Pyrénées* (1855) showed his mastery of orderly and minute observation. Thus he compelled recognition, and the government that had thought him dangerous in 1854 made him professor in the Ecole des Beaux-Arts in 1864. Here he gave several series of lectures on the history of art that are models of philosophic criticism and, applying the same principles in

another field, published a monumental *Histoire de la littérature anglaise* (1864). Then followed *Idéalisme anglais* (1864); *Positivisme anglais* (1864), the latter a study of J. S. Mill; *Philosophie de l'art* (1865); *Philosophie de l'art en Italie* (1866); *Voyage en Italie* (1866-72); *L'idéal dans l'art* (1867); the cynically amusing *Notes sur Paris* (1867); the important *De l'intelligence* (1870); *Notes sur l'Angleterre* (1872); and finally his greatest work, *Origines de la France contemporaine*, consisting of *Ancien régime* (1875), *La révolution* (1878-84), and *Régime moderne* (1890). Most of his works have been translated into various languages.

Taine was the theorist of naturalism, of immense yet systematized erudition, and of a logic that was almost mechanical. He represents in criticism the scientific spirit that was making itself felt almost simultaneously in all branches of French intellectual activity, in the poetry of the Parnassians, the philology of Renan, the fiction of Flaubert, the dramas of the younger Dumas, the high art of Meissonnier, and the low art of Forain. The analytic, meticulous spirit of his generation found in his "little facts, well chosen, important, significant, amply substantiated, minutely noted, the material of every science." He sought to make psychology, æsthetics, and literary criticism into exact sciences, capable of rigorous analysis and systematic deduction. His is always the interest of the naturalist, not of the artist. The style was like the man and like the philosophy, grave, sincere, simple, almost always serene. There is in his work hardly a trace of irony, of strain, or of enthusiasm, none at all of sentimentality or of mysticism. His system may not have been deep, but it was wonderfully opportune, and Taine was a guiding light to the intellectually productive men of France almost until his death. Oxford gave him an honorary degree of LL.D. in 1871. He was tardily elected to the French Academy in 1878.

**Bibliography.** *H. Taine: sa vie et sa correspondance* (3 vols., Paris, 1902-05; Eng. trans. by Devonshire, London, 1902-08); Paul Bourget, *Essais de psychologie contemporaine*, vol. i (Paris, 1887); Jules Lemaitre, *Les contemporains*, vol. iv (ib., 1890-92); M. E. Boutmy, *Taine, Scherer, Laboulaye* (ib., 1901); V. Giraud, *Hippolyte Taine* (ib., 1901); P. Lacombe, *La psychologie des individus et des sociétés chez Taine* (ib., 1906); A. Aulard, *Taine, historien de la révolution française* (ib., 1907); F. B. Gummere, in *Democracy and Poetry* (Boston, 1911).

**TAINTER, CHARLES SUMNER** (1854- ). An American inventor. He was born at Watertown, Mass., and was educated in the public schools. In 1874 he was a member of the United States Transit of Venus Expedition to the Southern Pacific. He became known chiefly for his invention of a graphophone, for which he was made an Officer of Public Instruction (France) in 1889 and was awarded the John Scott medal by the city of Philadelphia in 1900. Tainter was also associate inventor of the radiophone, an instrument for transmission of sounds by the agency of light, and for his work in this connection was awarded a gold medal at the Paris Electrical Exhibition (1881).

**TAI-PEH**, tî'pâ', or **TAI-PAK**, tî'pâk' (pronounced by the Japanese *Dai-hokû*, dîhōkû). The capital of the Japanese island of Formosa (q.v.). It is a small walled city, about 13

miles from Tamsui (q.v.), with which it is connected by rail as well as with Kelung (q.v.). Near it is found the large and populous town of Bangka or Mangka, the centre of the tea trade. The total population of Tai-peh proper and of the suburbs was, in 1911, 99,208, including nearly 6000 Japanese.

**TAIPING** (tî'pîng') **REBELLION** (1850-64). The greatest civil war of Chinese history. It started as an obscure religious movement and soon changed into a revolt against the Manchu monarchy. It spread rapidly over south China, and by 1853 the old capital of Nanking was captured. An expedition against Peking failed. The organization of an Imperial army corps on modern military principles by the American Ward (died 1863), who was succeeded by General Gordon, practically saved the Manchu dynasty. By July, 1864, Nanking was recaptured and the rebellion collapsed. Estimates of the number of people killed in the revolt run into the millions (some authorities say 20,000,000), while the property and economic loss to China is incalculable. See CHINA, *Modern History*; HUNG SIU-TS'UEN; MANCHUS; WARD, F. T.

**TAIRA**, tî'â-rû. A Japanese clan of Imperial descent, one of the four great families, Fujiwara, Minamoto, and Tokugawa being the others, which have been most distinguished in the history of Japan. The Taira family was established in the ninth century, when some of its members were given the control of provinces in the west. In 814 another house, the Minamoto, also of Imperial descent, had been put in control in the east. For centuries the Taira and the Minamoto were content in their respective spheres, but in the twelfth century they came into conflict over the succession to the Imperial throne. The head of the Taira was Kiyomori, a man of great ability and of large experience in warfare. He was successful in his plans, defeated the Minamoto, and made himself supreme in the Empire. He took the office of Prime Minister from the Fujiwara family, married his daughter to the Emperor, filled all important offices with his clansmen, humiliated the Fujiwara nobles, and attempted the extermination of the Minamoto family. After his death, in 1181, the Minamoto clan obtained possession of the eastern part of Japan and then of Kyoto. The Taira retreated westward, were pursued by Yoshitsune, and finally defeated in 1185 in the sea fight of Dan-no-Ura. The clan was nearly exterminated and never regained its importance.

**TAIRA**, tî'rá. A South American weasel-like carnivore. See **TAIRA**.

**TAIREN**, tî'rén'. The Japanese name for Dalny (q.v.).

**TAI SHAN**, tî'shân'. The most easterly of the Five Yo or great sacred mountains of China, whose worship goes back into the fabulous period of Chinese history. It is a great massive complex of rugged limestone ridges, buttressed on the east and southeast by the mountains and hills which cover most of the Shantung peninsula. Its highest peak is 4111 feet above the level of the sea. It is about 60 miles south-southeast of Tsinanfu, the capital of Shantung (q.v.), and is dotted, especially on the south side, with Buddhist and Taoist temples, monasteries, and pavilions. It is annually visited by tens of thousands of pilgrims from all parts of the country.

**TAIT**, tāt, ARCHIBALD CAMPBELL (1811-82). Archbishop of Canterbury. He was born in Edinburgh and was brought up as a Presbyterian. During his studies at the University of Glasgow (1827-29) he determined to enter the ministry of the Church of England and went up to Balliol College, Oxford, in 1830. He took his degree there (1833), was fellow (1834), and ordained (1836). He refused to be carried away by the Oxford movement and joined with three other tutors in a famous protest against the principle involved in Tract XC. In 1842 he succeeded Dr. Arnold as head master of Rugby, which he left in 1850 for the deanery of Carlisle. He was a member of the important Oxford University Commission (1850-52). In 1856 he became Bishop of London and, amid the difficulties of times full of bitter controversy, won the respect of all by his devotion and impartiality. The same may be said of his administration of the primacy, on which he entered at the beginning of 1869. Though liberal in sympathy, he was tolerant towards the ritualists throughout the excitement which caused the passing of the Public Worship Regulation Act in 1874, and on all questions showed independence and firmness. Consult: A. C. Bichley, *Public Life of the Late Archbishop of Canterbury* (London, 1883); Davidson and Benham, *Life of Archibald Campbell Tait* (2 vols., ib., 1891); James Bryce, *Studies in Contemporary Biography* (New York, 1903); Paul Thureau-Dangin, *English Catholic Revival in the Nineteenth Century* (2 vols., London, 1914).

**TAIT**, SIR MELBOURNE McTAGGART (1842-). A Canadian jurist. He was born at Melbourne, Province of Quebec, studied at St. Francis College, and graduated in law at McGill University in 1862. Called to the bar in 1863, he practiced his profession at Richmond and later in Montreal, where he became a partner of Sir J. J. C. Abbott and a leader of the provincial bar. He was appointed a puisne judge of the Superior Court of the Province of Quebec in 1887, Assistant Chief Justice thereof in 1894, and was Chief Justice from 1906 until 1912, when he retired. In 1897 he was knighted.

**TAIT**, PETER GUTHRIE (1831-1901). A Scottish physicist, born at Dalkeith and educated at Edinburgh University and Peterhouse, Cambridge, where he was made a fellow in 1852. He was appointed professor of mathematics in Queen's College, Belfast, in 1854, and was professor of natural philosophy in the University of Edinburgh from 1860 to the time of his death. He carried on many important investigations in mathematics and physics, particularly on the mathematical and theoretical side of the latter science. His most famous work in mathematics was on quaternions, while his studies in thermodynamics and thermoelectricity were of unusual value. His papers on the kinetic theory of gases are among his many important contributions to science, and his works cited below are marked by conciseness and lucidity of statement. He was the author of *Dynamics of a Particle* (1865); the important *Natural Philosophy* (1867), with Lord Kelvin (then Sir William Thomson); *Quaternions* (1867); *Thermodynamics* (1868); *Recent Advances in Physical Science* (1876); *Heat* (1884); *Light* (1884); *Properties of Matter* (1885); *Dynamics* (1895). He also wrote, with Balfour Stewart (q.v.), *The Unseen Universe* (1875; new ed., 1901). His *Scientific*

*Papers* were collected in two volumes (1899-1900). Consult C. G. Knott, *Life and Scientific Work of P. G. Tait* (Cambridge, 1911).

**TAIT**, ROBERT LAWSON (1845-99). A British gynecologist, born and educated at Edinburgh. He settled in 1870 in Birmingham, where he became the leading gynecologist of his time and country. A violent opponent of Lister and his theory, he asserted that there was no connection between bacteria and disease. He performed hundreds of gynecological operations with hardly a death, the secret of his success lying partly in his great skill and partly in the use of warm or boiled water for flushing the field of operation—in reality this was the best asepsis. In 1879 Tait first excised the normal ovaries and thus became the pioneer in this kind of gynecological operation. Among many important operations he introduced hepato-my in 1880. Besides numerous essays he published carefully prepared statistics on his operations. He stated it as a rule in medicine that an exploratory laparotomy should be performed in every case of obscure abdominal or pelvic disease that seemed to threaten life.

**TAI-TSU**. See ILUNG-WU.

**TAITTIRIYA**, tī'tē-rē'yā (Skt., from *Taittiri*, name of an ancient Hindu sage). The title of a school and of a redaction of the Yajur-Veda. See VEDA.

**TAIWAN**, tī'wān' (Chin., terraced bay). The name by which the island of Formosa (q.v.) is known to both the Chinese and the Japanese.

**TAIYUENFU**, tī'yūn-ū'fū, or **TAIYUEN**. A walled city of China, capital of the Province of Shansi (Map: China, K 4). It stands between loess-covered hills near the head of a fertile plain, 30 or 40 miles wide, about 70 miles long, 3000 feet above the level of the sea. Both coal and iron are worked near the city on the west, and there are silver mines about 65 miles north. The coal is bituminous and is of fine quality. The city consists, like Peking, of an inner and an outer city, the inner on the north and the outer on the south. The former measures 2½ miles by 1½, is surrounded by walls of moderate height, and has eight gates with towers over each and on the corners. The outer city is surrounded by mud walls, with three gates, one of which was kept closed for Imperial use. Among the buildings worthy of mention is the Wan-Show Kung (palace of ten thousand ages), arranged as a temple, roofed with yellow tiles, and containing one room. The city has one of the best educational institutions in China, known as Shansi University. Taiyuenfu also possesses a gun and cannon foundry. Pop., 250,000.

**TAJACU**, tī'yā-sū'. See PECCARY.

**TAJIKS**, tā-zhēks'. The term applied particularly to the rural population of eastern Persia and generally to their representatives and congeners scattered from Constantinople to the borders of China and from Orenburg to the Indian Ocean. It is sometimes more of a descriptive than a racial epithet. There are "mountain Tajiks" and "Tajiks of the Plain"—the Galchis (q.v.) of the Pamir being also known as "mountain Tajiks." The tajiks are rather above the average in height, brachycephalic, and show traces of Turkish intermixture. Consult Henry Houssay, *Les races humaines de la Perse* (Paris, 1887), and Ujfalvy, *Les Aryens au nord et au sud de l'Hindou Kouch* (ib., 1896).

**TAJ MAHAL**, tāj mā-hāl' (Pers., crown of Mahal). A mausoleum of white alabaster, a mile east of Agra (q.v.), India, built (1629-50) by Shah Jehan as a burial place for his favorite wife, Mumtaz-i-Mahal. It is said to have cost over \$9,000,000. The building is octagonal, 130 feet in length and width and 70 feet high, exclusive of the dome, which rises 100 feet above the main mass. Four exquisite cylindrical minarets, 133 feet high, mark the corners of the superb platform on which it stands. In the central chamber, above the vault containing the bodies of the Emperor and his wife, are two cenotaphs surrounded by an alabaster screen of delicate open-work inlaid with precious stones. The interior is lighted by the diffused daylight which filters through the translucent alabaster of the dome and through windows fitted with perforated alabaster screens. The exterior is covered with arabesques and passages from the Koran in inlays of precious stones. The whole edifice on its platform is set in a foursquare inclosure adorned with a magnificent gateway and two mosques, all of red sandstone and white marble. The Taj is unquestionably the most beautiful edifice of the seventeenth century in any land, and the supreme achievement of Mohammedan art (q.v.).

**TAKABE**, tā'kā'bā, HIKOJIRŌ KENKŌ (1664-1739). A distinguished Japanese mathematician, born in Tokyo (then Yeddo). He was the favorite and most distinguished pupil of Seki (q.v.) and was very influential in making the *yenri* (circle principle), or native Japanese calculus, known to his countrymen.

**TAKAHASHI**, tā'kā-hā'shē, KOREKIYO, BARON (1854- ). A Japanese financier, born in Yeddo. He studied in America in 1867-68, became an official in the Japanese Department of Agriculture and Commerce in 1881, and later was director of the Patent Bureau. Between 1892 and 1913 he was connected with the Bank of Japan, for several years being its governor. After 1906 he was also president of the Yokohama Specie Bank. He visited England and America twice between 1904 and 1906 to arrange loans in connection with the Russo-Japanese War, and for his services was created Baron in 1907. He served as Minister of Finance in 1913-14.

**TAKAHIRA**, tā'kā-hē'rā, KOGORO (1854- ). A Japanese diplomat, born in Iwate. He held several minor positions, was Consul General at New York in 1887, and after acting as Minister at The Hague, Rome, and Vienna, and as Assistant Foreign Minister (1899), was Minister at Washington (1900-05). He served as the junior Japanese plenipotentiary at the Portsmouth Peace Conference in 1905. Takahira was created Baron in 1905 and became a member of the House of Peers in 1906. He was appointed Ambassador to Italy in 1907 and served in the same capacity at Washington in 1908-09.

**TAKAMATSU**, tā'kā-māt'su. The capital of the Prefecture of Kagawa in Japan, on the north coast of Shikoku (Map: Japan, D 6). It has a fine landscape garden in its southern suburb. Pop., 1908, 42,578.

**TAKAMINE**, tā'kā-mē'nē, JOKICHI (1854-1922). A Japanese-American chemist. He was born in Takaoka, Japan, and graduated (1879) as a chemical engineer at the University of Tokyo, afterward studying for two years at Glas-

gow. In 1881 he was made chief chemist of the Japanese Department of Agriculture and Commerce and later was Assistant Commissioner of the Patent Office. In 1890 he came to the United States and established a research laboratory in New York City. He gave much attention to the study of diastatic ferments and produced takadiastase, used as a starch digestant. With Aldrich he also isolated adrenalin (q.v.). Honors came to him from Japanese and other societies.

**TAKAMORI**, SAIGO. See SAIGO TAKAMORI.

**TAKAO**. See TAKOW.

**TAKAOKA**, tā'kā-ō'kā. A town in the Prefecture of Toyama, central Hondo, Japan, 10 miles by rail northeast of Kanazawa (Map: Japan, E 5). It manufactures dyes and hardware. Pop., 1908, 33,603.

**TAKASAKI**, tā'kā-sā'kē. A town in the Prefecture of Gumma, central Hondo, Japan, situated 63 miles by rail northwest of Tokyo (Map: Japan, F 5). It has manufactures of cotton and silk. Pop., 1898, 30,893; 1908, 39,961.

**TAKASHIMA**, tā'kā-shō'mā. A small island of Japan, about 8 miles southwest of the entrance to the harbor of Nagasaki (Map: Japan, J 2). It has an extensive coal mine, which dates from the middle of the eighteenth century.

**TAKATA**, tā'kā'tā. A town in the Prefecture of Niigata, north Hondo, Japan, 42 miles by rail north of Nagano. It has extensive manufactures of cotton goods (Map: Japan, F 5). Pop., 1898, 20,315; 1908, 28,021.

**TAKELMA**, tā-kēl'mā, or **TAKILMAN** (tā-kil'man) **STOCK**. A small linguistic family of Indians in southwestern Oregon, with a culture similar to that of other northern California tribes. They were reduced to a single representative in 1910. Consult Sapir, *American Anthropologist*, vol. ix (1907).

**TAKIN**, tā'kēn, or GNU GOAT. A goatlike animal (*Budorcas tamicolor*) of eastern Tibet, allied to the serow (q.v.), but having horns (in both sexes) bent at right angles.

**TAKOW**, or **TAKAO**, tā'kou'. A village on the west coast of Formosa, thrown open in 1864 by the Chinese for foreign residence and trade and continued as a treaty port by the Japanese (Map: Japan, D 9). It lies 20 miles south of Tainan (q.v.), with which it is connected by rail, and on the edge of a fertile plain inhabited chiefly by immigrants from Kwangtung and producing good crops of rice, sugar, etc. There is a considerable export of sugar. Pop., 1911, 14,649.

**TAK-TI-KESRA**. See CTESIPHON.

**TAKU**, tā'kou'. A village in the Province of Chihli, north China, near the mouth of the Pei-ho, 30 miles east of Tientsin (Map: China, L 4). It is known for its strong fortifications, which were taken by the British and French in 1860 and by the allied troops on June 17, 1900, during the Boxer uprising.

**TAKU**, tā'kou. See TLINKIT.

**TAKULLI**. See TACULLI.

**TALAING**, tā-lū'ing. See INDO-CHINESE; KLINGS; MONS.

**TALAVERA DE LA REINA**, tā'lā-vā'rā dā lā rā'ē-nā. A town of New Castile, Spain, in the modern Province of Toledo, 83 miles by rail southwest of Madrid, on the Madrid-Valencia de Alcántara Railroad (Map: Spain, C 2). It is charmingly situated on the right bank of the Tagus, which is here spanned by a quarter-

mile bridge of 35 arches. The town is in a fertile, well-watered valley and boasts a silk-weaving industry, important potteries, and cloth, hat, leather, soap, and varnish factories. Pop., 1900, 9990; 1910, 12,357. An important battle took place here July 27 and 28, 1809, in which Wellington and the Spanish forces defeated the French under Joseph Bonaparte, Jourdan, and Victor.

**TALBOT**, tal'büt. See **HOUND**.

**TALBOT**, ARTHUR NEWELL (1857- ). An American civil engineer. He was born at Cortland, Ill., and was educated at the University of Illinois (B.S., 1881; C.E., 1885). He engaged in civil-engineering work and made investigations of steel, brick, reinforced concrete, and other materials of construction. After 1890 he was professor of municipal and sanitary engineering and in charge of theoretical and applied mechanics at the University of Illinois. Talbot served as president of the Society for the Promotion of Engineering Education in 1910-11 and of the American Society for Testing Materials in 1913-14. He wrote: *The Railway Transition Spiral* (3d ed., rev., 1901); *Tests of Concrete* (1906); *Tests of Reinforced Concrete Beams* (1909); *Tests of Columns* (1912); *Tests of Reinforced Concrete Buildings under Load* (1913).

**TALBOT**, CHARLES, twelfth EARL and only DUKE OF SHREWSBURY (1660-1718). An English statesman. He was the son of the eleventh Earl, his mother being the notorious Anna Maria Brudenell, the mistress of the Duke of Buckingham, who in a duel killed Charles's father. He was educated as a Roman Catholic, but after the Popish Plot attached himself to the Anglican church. Although a prominent official at the coronation of James II in 1685, he was one of the seven noblemen who invited William, Prince of Orange, to England. He was Secretary of State for the northern province from 1689 to 1690 and again in 1694, on the latter occasion being made Knight of the Garter and created Marquis of Alton and Duke of Shrewsbury. In 1710 he was appointed Lord Chamberlain by Queen Anne, in 1712 Ambassador to France, and in 1713 Lord Lieutenant of Ireland. Two days before her death, in 1714, the Queen appointed him Lord High Treasurer. Under George I he was Lord Chamberlain.

**TALBOT**, HENRY PAUL (1864-1927). An American chemist. He was born in Boston, Mass., and graduated in 1885 at the Massachusetts Institute of Technology, where by 1902 he had become professor of inorganic and analytical chemistry, with charge of the department of chemistry and chemical engineering. In 1890 he had taken his Ph.D. at Leipzig. During 1892-94 he lectured on chemistry at Wellesley College. He published many papers in technical chemistry, on which he became an authority, and *Introductory Course of Quantitative Chemical Analysis* (1897); *Bibliography of the Analytical Chemistry of Manganese* (1902); *The Electrolytic Dissociation Theory* (1905), with A. A. Blanchard.

**TALBOT**, JOHN, first EARL OF SHREWSBURY (c.1388-1453). An English general of Welsh descent. Henry V appointed him Lord Lieutenant of Ireland in 1414, where he was engaged in subduing some of the septs and in other military operations. In 1419 he went to France and took an active part at the sieges of Melun and Meaux and in the battle of Verneuil. In

1424 he received the Order of the Garter and again became Lord Lieutenant of Ireland under Henry VI. In 1427 he again returned to France and after numerous successes in Brittany was taken prisoner at Patay in 1429 by Joan of Arc. The ransom demanded for his release was so high that he did not regain his freedom until 1433 and then by exchange. In 1442 he was created Earl of Shrewsbury and in 1446 Earl of Waterford, Lord of Dungarvan, and Steward of Ireland. With the exception of an interval of rule in Ireland from 1445 to 1447, the rest of his life was spent in France, where he was killed at the battle of Castillon in 1453.

**TALBOT**, JOHN (1645-1727). One of the early Church of England missionaries in America. He was rector of Freeethorne, but resigned his living to come to America with the first missionaries sent by the Society for the Propagation of the Gospel. He was the founder and first rector of St. Mary's Church, Burlington, N. J., and labored diligently there and in other Colonies. There is considerable evidence for believing that he was consecrated Bishop by the Nonjurors (q.v.) in 1722, 60 years before Seabury obtained consecration from the Scottish bishops. Talbot is said occasionally to have assumed the episcopal dress and to have administered confirmation privately. In 1724 he was forbidden to officiate because he refused to take the oath of allegiance. Consult Hills, *John Talbot, the First Bishop of North America* (Trenton, 1878), and id., *History of the Church in Burlington* (2d ed., ib., 1885).

**TALBOT**, RICHARD, DUKE and EARL OF TYRCONNEL. See TYRCONNEL, RICHARD TALBOT, DUKE and EARL OF.

**TALBOT**, SILAS (1751-1813). An American naval officer, born in Dighton, Mass. He was engaged, as a boy, in the coasting service and in June, 1775, after the outbreak of the Revolutionary War, entered the American army as lieutenant, serving at Boston and becoming a captain of infantry in January, 1776. At New York in 1776 he made an attempt, by means of a fire ship, to destroy a part of the English squadron in the harbor, and on Oct. 7, 1777, Congress promoted him to the rank of major. He was wounded (Oct. 23, 1777) at Fort Mifflin, served with gallantry at Butt's Hill (Aug. 29, 1778), and on Oct. 28, 1778, in command of a small sloop, captured off Newport the British blockading schooner *Pigot*. For this he was commissioned lieutenant colonel by Congress on November 14. He became a captain in the United States navy Sept. 17, 1779, and was directed to protect the Long Island coast and to keep General Gates's communications open. In May, while in command of the *Pigot* and the *Argo*, he captured the British schooner *Lively* and two privateers, and subsequently defeated and captured the *King George* and the *Dragon*, the latter after a four hours' battle. He was taken by the British in 1780 and treated with severity, being confined in the prison ship *Jersey* and afterward in the Old Sugar House, and then being taken to England, where he was exchanged in 1781. After the war he was a member of Congress (1793-94). The frigate *Constitution* (q.v.) was built under his supervision and in 1799 was his flagship during a cruise in the West Indies. Owing to a dispute with Commodore Truxtun concerning priority in rank, he resigned in 1801. Consult Tuckerman, *The Life of Silas Talbot* (New York, 1850).

**TALBOT, WILLIAM HENRY FOX (1800-77).** An English photographer and philologist, known as one of the pioneers in photography. He was educated at Cambridge and for a short time was member of Parliament for Chippenham. The first problem to attract his attention was that of fixing shadows, and by patient research he was gradually led to the discovery of a process of obtaining and fixing sun pictures. On the dissemination of a report as to Daguerre's successes in the same field, Talbot secured his just rights by publishing a paper (*Phil. Mag.*, March, 1839) in which the successive steps of his investigation and their result were detailed. This process was subsequently improved by his invention (1841) of the calotype process. His discoveries and inventions in photography are described in his *Pencil of Nature* (1844-46). In later life he devoted himself to the study of philology and archaeology and was one of the first to read the cuneiform inscriptions of Nineveh. Among his works are: *Hermes, or Classical and Antiquarian Researches* (1828-39); *Illustrations of the Antiquity of the Book of Genesis* (1839); and a work on *English Etymologies* (1846). See CALOTYPE; PHOTOGRAPHY.

**TALC** (Fr. *talc*, Sp. *talco*, *talque*, from Ar. *talq*, *talc*). A silicate of magnesium containing a small percentage of water. It has a pearly or semimetallic lustre, is soft, and is silvery white to gray or green in color. Talc seldom occurs in crystals, and its system of crystallization is still in doubt; it is usually found in foliated or granular masses. Talc is an exceedingly common mineral and in some regions is found in large beds. The granular massive varieties are commonly known as soapstone and find extensive use in commerce as slabs for hearthstones, mantels, sinks, etc., and when powdered, as a pigment, in paper making, as a lubricator, for dressing skins and leather, etc. The fine granular or cryptocrystalline varieties are used for marking purposes under the name of French chalk. In 1913, 149,271 tons, valued at \$1,280,020, were mined in the United States.

**TALCA, tál'ká.** A province of Chile (Map: Chile, E 5). Its area is 3834 square miles. It is mountainous, with the Andes in the east and the lower coast range in the west, and the central portion is covered with plains interspersed with low hills. The mountains are well wooded, and the interior is very fertile. Wheat is the chief agricultural product, and grazing is carried on extensively. Pop., 1907, 132,155; 1910, 132,730.

**TALCA.** The capital of the Province of Talca, Chile, on the left bank of the Claro River, a tributary of the Maule, 140 miles south of Santiago on the Santiago-Concepción Railway (Map: Chile, E 5). It has a variable and disagreeable climate. The chief industry is the weaving of *ponchos* (woolen blankets). Pop., 1903, 43,331; 1912 (est.), 39,097.

**TALCAHUANO, tál'ká-wá'nó.** A seaport of Chile, on the Pacific coast, 9 miles north of Concepción. The town is located on a peninsula which partly incloses an excellent harbor, the entrance of which is protected by the island of Quiriquina and a breakwater. Government arsenals and dockyards are located here. Talcahuano will be the Pacific terminus of the transcontinental railway from Bahía Blanca, Argentina. Wheat grown in the interior provinces of Santiago and Valdivia, with which the town

has railway connection, is exported. Pop. 1912, 16,261. Talcahuano was founded as a military post in 1780 and was almost totally destroyed by an earthquake in 1835.

**TALC ROCK.** See SOAPSTONE.

**TALENT** (Lat. *talentum*, from Gk. *τάλαντον*, *talanton*, talent, weight, balance; properly, a supporter, as connected with *τλήναι*, *tlínai*, to bear, support, Lat. *tollere*, to lift, Skt. *tulā*, balance). The maximum unit of weight and value among the later Greeks; the equivalent of 60 minæ or 6000 drachmæ. In the Homeric poems the word is used to signify a small weight of gold (two talents are worth less than a handsome bronze caldron). While the name is Greek, the weight came from Babylonia and Phœnicia. There a system of 60 shekels to a mina (q.v.) and 60 minæ to a talent was employed in early times and in two forms, a common and a royal, the latter being about one-twentieth heavier than the common. Furthermore, both forms had a heavy and a light system. Moreover, in weighing gold, 50 shekels were reckoned to a mina, or 3000 instead of 3600 to a talent. For silver, again, a new standard was introduced, so arranged that while the ratio in value of silver to gold was 1 to 13½, the ratio of weight should be 1 to 10 (Babylonian) or 1 to 15 (Phœnician). The royal forms seem also to have varied at different times. The Greeks, in borrowing these systems, naturally varied them somewhat, and we therefore find considerable variety among the different Greek states. A very slight variation in the weight of the shekel, or drachma, would make a large difference in the talent. Of the chief Greek systems the Æginetan is not exactly identical with any of the Eastern standards, but is perhaps connected with a Babylonian royal form, and at any rate seems to have been adapted to the trade of Ægina with Asia Minor. This talent weighed about 37.8 kilograms. The other common standard was the Euboic-Attic with a talent of about 26 kilograms, which has been usually connected with the common light Phœnician standard, though recent writers prefer to connect it with the Babylonian. In Athens this was used in reckoning money, while in the market a talent of about 37 kilograms was employed. The value of the Attic silver talent, which was not a coin but a sum of money, was about \$1080. Consult the article "Pondera," in William Smith, *A Dictionary of Greek and Roman Antiquities*, vol. ii (3d ed., London, 1891), and G. F. Hill, *Handbook of Greek and Roman coins* (ib., 1899). See DRACHMA; MINA; SHEKEL.

**TALENTI, tà-lén'té.** The name of two Florentine architects, father and son. FRANCESCO TALENTI, the father, was probably born about 1305 at Pontelieve, near Florence, and was employed as early as 1329 on the cathedral of Orvieto. He appears to have succeeded Taddeo Gaddi as architect of the campanile of the cathedral of Florence, begun by Giotto (q.v.), of which he built the upper three stories. In 1555 he was employed to make a new and enlarged design for the nave of the cathedral, which was built after his model and nearly completed at his death (c.1370).

His son SIMONE assisted him in preparing the model and in 1375 was appointed chief architect of the cathedral. In association with Benci di Cione, Simone designed the Loggia dei Lanzi and supervised the greater part of its erection.

He also designed the lower part, at least, of the granary church of the Or San Michele. The dates of his birth and death are not known.

**TALE OF A TUB.** 1. A comedy by Ben Jonson, licensed in May, 1633, and printed in folio in 1640. 2. A religious satire by Jonathan Swift, published anonymously in 1704. It deals with the various alterations which three brothers make in the coat which their father has bequeathed to them. Peter stands for the Roman Catholic church, Martin for the Lutherans, and Jack (from John Calvin) for the extreme Protestants.

**TALE OF TWO CITIES.** A. An historical novel by Charles Dickens, first published serially in *All the Year Round* in 1859, and later in book form. Its scene is laid partly in London and partly in Paris during the French Revolution. See DEFARGE, THÉRÈSE.

**TALE SAP.** See TONLE SAP.

**TALES'MEN** (from Lat. *tales*, nom. pl. of *talis*, such, from the initial word in the summons of the original Latin phrase *tales de circumstantibus*, such of the bystanders + Eng. *men*). Men called to supply a deficiency in the number of jurors in a panel. In some jurisdictions a list of competent men is kept by the proper officials for this purpose, and in many States, in an emergency, the court may call upon bystanders to fill the panel. Jurors thus summoned are called talesmen. See JURY.

**TALES OF A GRANDFATHER.** A collection of historical pictures, by Sir Walter Scott, of England, Scotland, and France.

**TALES OF A TRAVELER.** A series of sketches and stories by Washington Irving (London and New York, 1824), the scenes of which are laid in England and France.

**TALES OF A WAYSIDE INN.** A collection of poetical narratives by Henry Wadsworth Longfellow (q.v.), published in three parts in 1863, 1872, and 1873, later combined. The Wayside Inn was an old tavern at Sudbury, Mass., where three of the characters of the *Tales* spent their summers—T. W. Parsons, Luigi Monti, and Daniel Treadwell (q.v.). The other persons introduced include Ole Bull (q.v.) as the Musician, Israel Edrehi as the Spanish Jew, and Henry Ware Wales as the Student.

**TALES OF MY LANDLORD.** The name given by Sir Walter Scott to four different sets of his novels. Their publication was begun in 1816 under the fictitious editorship of Jedediah Cleishbotham (q.v.). The first set contained *The Black Dwarf* and *Old Mortality*; the second (1818), *The Heart of Midlothian*; the third (1819), *The Bride of Lammermoor* and *The Legend of Montrose*; and the fourth (1832), *Count Robert of Paris* and *Castle Dangerous*.

**TALES OF THE CRUSADERS.** The name given by Sir Walter Scott to *The Betrothed* and *The Talisman* (1825).

**TALES OF THE GENII.** A series of Oriental stories, modeled on the *Arabian Nights*, by James Ridley, published in London in 1764.

**TALFOURD,** tál'fôrd, SIR THOMAS NOON (1795-1854). An English lawyer and author, born at Reading in Berkshire. He studied law with Joseph Chitty (q.v.) and was called to the bar at the Middle Temple (1821). He was eventually elected to the bench in the Court of Common Pleas (1849). His famous case was a defense of Edward Moxon, who was prosecuted for publishing Shelley's *Queen Mab*. Entering Parliament in 1835, he championed the copyright

bill (1837), which he himself had introduced. In recognition of his service *Pickwick* was dedicated to him. With Lamb his name is especially associated by *Letters of Charles Lamb with a Sketch of his Life* (1837) and *Final Memorials of Charles Lamb* (1848). In 1875 these two books were published together under the title *Memoirs of Charles Lamb*. They have since been edited by Percy Fitzgerald (London, 1892). Talfourd's great literary success was *Ion*, a tragedy performed by Macready (May 26, 1836). It was followed by *The Athenian Captive* (1838) and *Glencoe* (1840). Consult the *Tragedies* (Routledge's Pocket Library, New York, 1889); *Critical and Miscellaneous Writings* (Philadelphia, 1842); his essays in *Modern British Essayists*, vol. vii (ib., 1848-50); and *A Memoir of Mr. Justice Talfourd* (London, 1854).

**TALIAFERRO,** tál'yá-fér'rô, MABEL (1887- ). An American actress, born in New York City. She first appeared on the stage when two years old and played child parts with J. A. Herne in *Shore Acres*, and with Chauncey Olcott. She first attracted notice as Esther Ansell in *The Children of the Ghetto* (1899). Other rôles included Lovey Mary in *Mrs. Wiggs of the Cabbage Patch* (1903); Polly in *Polly of the Circus* (1907), a great success; Edith in *My Man* (1910). In 1913-14 she played in *Young Wisdom*. Her sister, EDITH TALIAFERRO, also became known as an actress.

**TALIAFERRO,** tál'y-vër, WILLIAM BOOTH (1822-98). A Confederate soldier, born at Belleville in Gloucester Co., Va. He attended Harvard College and graduated at William and Mary College in 1841. At the beginning of the Civil War he was made a colonel in the provisional Army of Virginia. He participated in most of the battles fought by the Army of Northern Virginia prior to March, 1863, and was promoted brigadier general in March, 1862. In March, 1863, he was put in command of the district of Savannah, Ga. In the following July, at the time of the desperate attacks on Fort Wagner, he was in command of the defenses on Morris Island and in August of those on James Island. In 1864 he commanded the Seventh Military District, comprising a part of South Carolina, and in December was given command of the entire State. He was promoted major general Jan. 1, 1865. After the war he resumed the practice of law and served for 10 years in the Virginia House of Delegates.

**TA-LIEN-WAN,** tál'i-ên'wän'. A bay on the east coast of the Liaotung Peninsula in Manchuria (Map: China, M 4). It is deep, roomy, ice-free throughout the year, and protected at the entrance by two islets. At its head lies the port of Dalny (q.v.), or Tai'en. Ta-lien-wan with the surrounding territory was leased by China to Russia in 1898 and surrendered to Japan in 1905.

**TALIESIN,** tál'i-sín. A British bard, who is supposed to have lived about the middle of the sixth century. Nothing definite is known as to his career, and some scholars hold that he is a mythical personage. According to legend he was called "the chief of the bards." The "Book of Taliesin" contains 56 poems, which were formerly attributed to Taliesin. All are now generally believed to be of a later date. Consult W. F. Skene, *The Four Ancient Books of Wales* (2 vols., Edinburgh, 1868), in which the "Book of Taliesin" is included; for the legends, Lady Charlotte Guest, *Mabinogion* (London, 1902).

**TALIPES**, tāl'ī-pēz. The technical term for clubfoot (q.v.).

**TALIPOT PALM** (Hind. *tālpāt*, from Skt. *tālapatra*, palm-tree leaf, from *tāla*, palm tree + *patra*, leaf), **GREAT FAN PALM** (*Corypha umbraculifera*). The noblest palm of the East Indies, a native of Ceylon, Malabar, etc. Its straight cylindrical trunk, 40 to 80 feet high, is crowned with a tuft of enormous palmate plaited leaves, divided near the outer margin into numerous segments, and united to the trunk by spiny leafstalks. The leaves are usually about 10 to 20 feet in diameter, exclusive of the leafstalk, which is 7 or 8 feet long. At the age of 30 or 40 years the tree produces a long pyramidal cluster of whitish flowers, rising to the height of 30 feet from the midst of its crown of leaves, and dividing into simple alternate branches, the lower of which sometimes extend laterally 20 feet. After maturing the numerous globose fruits (about 1½ inches in diameter) the tree generally dies. The leaves are used for covering houses, for making tents, and for many other purposes. The leaves of this palm are used in Malabar for writing upon, characters being traced with an iron style. They are prepared for this by boiling, drying, damping, rubbing, and pressing. The soft central part of the stem yields a kind of sago. The large ivory-like seeds are used for making buttons, ornaments, etc.

**TALISAY**, tā'lē-sī'. A town of Cebu, Philippines, situated 6 miles southwest from Cebu, near Lipata Point. Pop., 1903, 13,636

**TALISMAN**, tāl'is-man or tāl'iz- (Sp., Portug. *talismán*, from Ar. *tilsam*, *tulsam*, *tilism*, pl. *tilsamān*, talisman, from Gk. *τέλεσμα*, *telesma*, consecrated object, talisman). In its strict sense, a species of charm, consisting of a figure engraved on metal or stone when two planets are in conjunction or when a star is at its culminating point, and supposed to exert some protective influence over the wearer of it by keeping away diseases or bringing luck. While the proper distinctive character of the talisman thus resides in its astrological character, in common usage the terms "talisman" and "amulet" (q.v.) are synonymous, referring to any object used as a charm against evil spirits or evil influences. Consult Elworthy, *The Evil Eye* (London, 1895).

**TALISMAN, THE**. A novel by Sir Walter Scott, published, with *The Betrothed*, in June, 1825. The action takes place in Palestine during the Crusades.

**TALITE**, tāl'īt. See MANNITE.

**TALKING MACHINE**. An apparatus designed to reproduce vocal, musical, and other sounds from appropriate records or by combination of various elemental sounds in some mechanical form. The reproduction of human speech has been a problem that has appealed to physicists and investigators for many years, but the complexity of sounds due to minute variations in pitch, as shown in the overtones as well as in the amplitude of the vibrations, has rendered this a difficult accomplishment. In the phonograph (q.v.) the vibratory movement of a diaphragm was transferred through the cutting stylus to a cylinder covered with tin foil, and when this operation was reversed, a corresponding movement of the same or another diaphragm resulted in the reproduction of the original sound. The improvement of the phonograph, especially the use of a wax record cylinder or disk, has made possible a wide variation of its applications. It has been used to record

sound reproduction for record, for the transmission of intelligence, for use in dictation and transcribing, and in the rendering of vocal and instrumental music. In each of these, as well as in other fields, talking machines have been developed especially adapted for the purpose in view, and they have become widely employed and with considerable success. The greatest vocal artists of the opera and concert stage have recorded their voices for reproduction in this way. Instruction in modern languages, with the aim of securing the proper pronunciation and accent, thus can be carried on, and records of notable vocal utterances can not only be made permanent, but can be reproduced practically without limit through the manufacture of wax disks or cylinders on which the original record has been impressed. See GRAMOPHONE; GRAPHOPHONE; PHONOGRAPH.

**TALLADEGA CO.** A city and the county seat of Talladega Co., Ala., 60 miles by rail east of Birmingham, on the Southern, the Birmingham and Atlantic, and the Louisville and Nashville railroads (Map: Alabama, C 2). It is the seat of State schools for the deaf, dumb, and blind: of Talladega College (Congregational), an institution for colored students; of the Alabama Synodical College for Young Ladies (Presbyterian); and of a Presbyterian Orphans' Home. It contains a Carnegie library. Talladega has cotton mills, cottonseed-oil mills, a chemical plant, foundries and machine shops, and manufactures hosiery and fertilizers. It is a market for white marble. The city adopted the commission form of government in 1911. On the site of Talladega General Jackson, at the head of 2000 men, defeated a force of 1000 Creek Indians on Nov. 9, 1813, the Indians losing about 300 and the Americans 15 killed and 86 wounded. Pop., 1900, 5056; 1910, 5854.

**TALLAHASSEE**. The capital of Florida and the county seat of Leon County, 165 miles west of Jacksonville, on the Seaboard Air Line and the Georgia, Florida, and Alabama railroads (Map: Florida, B 1). It is finely situated on an eminence in the vicinity of several picturesque lakes and has wide and beautifully shaded streets. The Florida State College for Women (occupying a site overlooking the city), the Florida State Normal and Industrial College for colored students, the Lincoln High School for colored students and the Leon County High School are the leading educational institutions. The State Library has 9500 volumes, and there are also in the city the Supreme Court Library, with more than 7000 volumes, and the David S. Walker Library (formerly the University Library), with 6000 volumes. Other prominent features are the State Capitol, the county courthouse, the post office, and several parks. The district produces cotton, tobacco, and sugar cane and has dairying and stock-raising interests. Cottonseed oil, lumber, naval stores, iron products, and cigars constitute the principal manufactures. Tallahassee was laid out in 1824 on a site selected one year earlier as the seat of the Territorial government and was incorporated as a city in 1827. Pop., 1900, 2981; 1910, 5018.

**TALL BUILDINGS**. See STEEL SKELETON CONSTRUCTION.

**TALLEMANT DES RÉAUX**, tāl'mān' də ră'ō', GÉNÉON (1619-92). A French writer, born at La Rochelle and connected with the famous Rambouillet family. He took his degrees in law, but refused to go into the magistracy.

He employed his leisure in literary work, wrote verses in the taste of the time, and began a tragedy of *Œdipe*. He is chiefly remembered by his *Historiettes*, a series of biographical, anecdotal, and character sketches of contemporaries. Light, witty, cynical, less restrained than modern taste demands, they are an invaluable document of the period and particularly of the Hôtel de Rambouillet. They have been collected by Monmerqué, Levassesseur (1840), and Techener (1860). Tallemant also began the *Mémoires de la régence d'Anne d'Autriche*, intended to throw light upon the administration of Cardinal Mazarin. These have not come down to us.

**TALLEYRAND-PÉRIGORD**, tā'lā'rān'-pā'rē'gōr', CHARLES MAURICE, DUKE DE, PRINCE OF BENEVENTO (1754-1838). A French statesman, born in Paris. His father was an officer in the French army and fought through the Seven Years' War. Charles Maurice was the eldest son; on account of an accident in infancy which rendered him lame for life, he was trained for the Church at Saint-Sulpice, the Sorbonne, and Rheims. He showed brilliant talents, but neither moral purpose nor a calling for the Church. He obtained, however, several ecclesiastical benefices, among them the abbacy of Saint-Denis in the diocese of Rheims (1775) in the year of his ordination. Appointed agent general for the clergy in 1780, a lucrative and important post which brought him into close connection with the government, he began a serious apprenticeship in public business, but led a notoriously licentious life. In 1788 his administrative abilities secured for him the bishopric of Autun. As representative of his diocese in the States-General of 1789, he favored uniting with the Third Estate and thus won the good will of the popular party. He was one of the commission to draw up a constitution for the nation. He assisted in framing the Declaration of Rights, proposed (Oct. 10, 1789) the confiscation of Church property as belonging of right to the nation, and on Feb. 16, 1790, became President of the National Assembly. He was among the first of his order to take the oath to obey the constitution and urged the clergy of his diocese to follow his example. Excommunicated by the Pope, he was compelled to resign his bishopric. In January, 1792, Talleyrand was sent to London in a semi-official capacity, the object being to conciliate England. It was suspected that he was a person "disposed to serve the King," and he was put on the list of *émigrés*. He remained in England until January, 1794, then spent more than a year in the United States, and after the fall of the Terrorists procured the revocation of his banishment and in March, 1796, reentered Paris, having paved the way for a favorable reception by a series of adroit and judicious intrigues. He attached himself to the group of constitutionalists and in 1797, mainly through Madame de Staël's influence, was named Minister of Foreign Affairs.

Talleyrand shrewdly saw the significance of the rise of Napoleon Bonaparte, attached himself to the young Corsican, and became his ally and confidant in the coup of the 18th Brumaire, when the Directory was overthrown. After this Talleyrand, who had been reappointed Minister of Foreign Affairs by Bonaparte, directed his efforts towards consolidating the power and authority of his master. In diplomatic negotiations following the victories of France under the Consulate he had the principal part; he was the prime

mover in the execution of the Duke d'Enghien and assisted in the establishment of the Empire and in the organization of the Confederation of the Rhine. For these services he was made Prince of Benevento in 1806. He opposed Napoleon's disastrous policy with regard to England and soon after Tilsit (1807) laid down his office as Foreign Minister and after some intriguing retired from active life (1809), residing on his estates and preparing for the turn of the tide. When, after the French disasters of 1812, Europe rose against Napoleon, Talleyrand became the centre of a group of malcontents, whose influence grew with the advance of the allied armies, and finally communications were opened with the Bourbons. Talleyrand dictated to the Senate the terms of the deposition of Napoleon, and on the restoration of the Bourbons he became Minister of Foreign Affairs in the first government of Louis XVIII. He represented France at the Congress of Vienna and played there a game of masterly politics, working on the jealousies of the Powers and by appealing to the principle of legitimacy gaining solid advantages for France. He had succeeded in bringing about a secret alliance between Austria, Great Britain, and France against Russia and Prussia when Napoleon's return from Elba shattered his plans. Henceforth he had little part in public affairs. He resumed the office of Foreign Minister in May, 1814, after the Restoration, but soon resigned, owing to the hostility of the old nobility. After the July revolution Louis Philippe employed him as Ambassador at the English court, where he contrived to bring about a friendly feeling between the new monarchy and the English government and negotiated the Quadruple Alliance of 1834 between France, Great Britain, Spain, and Portugal. He returned to France in 1835 and died at Valençay, May 17, 1838. Talleyrand stands out preëminently as the type of the unscrupulous diplomat and politician. A skeptic in religion and a cynic in morals, he possessed a remarkable insight into the grosser nature of man and almost unexampled adroitness for playing on the lower motives. He had a rare talent for caustic epigram, and his disillusioned view of human nature is attested by numerous witty sayings which have become part of the world's narrower wisdom.

**Bibliography.** *Mémoires*, edited by the Duc de Broglie (5 vols., Paris, 1891-92; Eng. trans., by A. Hall, London, 1891-92); G. Pallain, *La mission de Talleyrand à Londres en 1792* (Paris, 1889); id., *Le ministère de Talleyrand sous le Directoire* (ib., 1891); id., *Ambassade de Talleyrand à Londres, 1830-31* (2 vols., ib., 1891), collections of his letters and dispatches. Pichot, *Souvenirs intimes de Talleyrand* (Paris, 1870); Lady Blennerhasset, *Talleyrand* (Eng. trans., by F. Clarke, 2 vols., London, 1894); Joseph McCabe, *Talleyrand: A Biographical Study* (London, 1906); Bernard de Lacombe, *Talleyrand and the Man* (Eng. trans., Boston, 1911).

**TALLIEN**, tā'lyān', JEAN LAMBERT (1769-1820). A French revolutionary leader, born in Paris. He was educated by his father's employer, the Marquis de Bercy. He early imbibed

the spirit of the Revolution, was attached to the *Moniteur*, and started a journal, *L'Ami des Citoyens*, in imitation of Marat's *Ami du Peuple*. His *Discours sur le caucous qui ont produit la révolution française* appeared in 1791. He acquired great influence with the people and became a leader in extreme and sanguinary measures. On Aug. 10, 1792, he was made secretary to the Revolutionary Commune of Paris, was later chosen to the Convention, and there became the apologist of Marat, voted for the death of Louis XVI, and was eager for the destruction of the Girondists (q.v.). Late in 1793 he was sent to Bordeaux as the representative of the Committee of Public Safety. A passion there conceived for Madame de Fontenay, whom he married Dec. 26, 1794, made him amenable to her influence, which was on the side of clemency. On March 22, 1794, he was chosen President of the Convention. Robespierre, who felt that he could not be trusted, denounced him in the Convention. Tallien recognized his danger and rallied the remnants of the Dantonists, Hébertists, and other factions against the government of Robespierre, Saint-Just, and Couthon, and brought about the events of the 9th Thermidor (July 27, 1794), which caused the fall of the triumvirate. Tallien became head of the Committee of Public Safety, lent his aid in suppressing the Revolutionary Tribunal and the Jacobin Club, and drew up the accusations against Carrier, Le Bon, and others of the Terrorists. He was a member of the Council of Five Hundred (1795-98), where, however, his influence rapidly diminished. He accompanied Bonaparte to Egypt, editing the official journal, *Décade Egyptienne*, and, when returning to France, was captured by an English cruiser and taken to England, where he was lionized by the Whigs (1801). Soon after he returned to France and was sent in 1805 as Consul to Alicante. He died in Paris, Nov. 16, 1820. Under the Directory Madame Tallien's salon was one of the most brilliant in Paris. While Tallien was absent in Egypt, she was divorced from him and married in 1805 Count de Caraman, afterward Prince de Chimay. Consult J. Turquan, *Souveains et grandes dames* (Paris, 1898), and Louis Gastin, *La belle Tallien* (ib., 1909). See CHIMAY, JEANNE MARIE IGNACE THÉRÈSE DE CABARRUS, PRINCESS DE.

**TALLIS, THOMAS** (c.1510-85). An English organist and composer. He achieved great proficiency in organ playing and was organist at Waltham Abbey for many years. About 1542 he was appointed gentleman of the chapel royal and served under Henry VIII, Edward VI, and the queens Mary and Elizabeth. He was also organist to Elizabeth. In 1575-76 he obtained, with William Byrd, letters patent giving the exclusive right for 21 years of printing music and ruled music paper. The first work printed under this patent was their *Cantiones quæ ab Argumento Sacræ Vocantur Quinque et Sex Partium* (London, 1575), containing 34 motets, by Tallis and Byrd, the work being a beautiful specimen of typography. About this time he composed his famous motet of 40 parts, *Spem in Alium non Habui*, adapted to English about 1630. Tallis's compositions consist of Church music, *Order of Daily Service*; *Full Cathedral Service*; *Order for Morning Prayer, with the Litany Noted* (all of which were edited in the nineteenth century); Te Deums, chants, hymns, motets, etc. His manuscripts are in the Oxford and Cambridge University libraries and in the British Museum.

**TALLMADGE, BENJAMIN** (1754-1835). An American soldier, born in Brookhaven, N. Y. He graduated at Yale in 1773; taught school at Wethersfield, Conn.; in June, 1776, became lieutenant and adjutant of a Connecticut regiment, rising to the rank of captain in December, 1776, and of major in April, 1777. On Sept. 5, 1779, without loss, he captured 500 Tory marauders at Lloyd's Neck, Long Island, and in May, 1780, captured Fort George at Oyster Bay. He was present at the battles of Brandywine, Germantown, and Monmouth, had the custody of Major André until that officer's execution, and served at Washington's headquarters in 1781-83. After the war he became a successful merchant at Litchfield, Conn. His *Memoirs* were printed privately by his son in 1850.

**TALLMADGE, NATHANIEL PITCHER** (1795-1864). An American legislator and governor, born in Chatham, N. Y. He graduated at Union College in 1815 and in 1818 was admitted to the bar. He served in the State Legislature (1828-33) and was then elected to the United States Senate as a Democrat. Afterward he allied himself with the Whigs and served by reelection until 1844, when he resigned to accept the appointment of Territorial Governor of Wisconsin, tendered him by President Tyler, and served until removed by President Polk in 1846.

**TALLOW** (MDutch *talgh*, *talch*, Dutch *talk*, Ger. *Talg*, tallow; possibly connected with AS. *talg*, color). A mixture of stearin, palmitin, and olein (qq.v.) derived from animal fat in the process of rendering. This fat is generally obtained from beef or mutton by melting and separation by heat, usually under pressure. It is no longer regarded exclusively as a mixture, but may be considered as a chemical union of its various ingredients. According to this belief the differing physical properties of tallow from various sources are actually due to variations in composition. From beef and mutton fats, distearo-palmitin, dipalmito-stearin, and dipalmitolein have been isolated. The natural form of tallow known as suet is still highly regarded as a fat food and is the source of edible stearin. Tallow is a white and almost tasteless substance in its pure condition, but the commercial article is usually of a yellowish color. It is insoluble in water and has a specific gravity which varies from 0.925 in the case of beef tallow to 0.937 in the case of mutton tallow. It melts between 100° F. and 120° F. Tallow is employed in making candles (q.v.) and soap. It may also be used as a lubricant. Tallow substitutes of synthetic composition are produced from various oleins by the process of hydrogenation. See FATS.

**TALLOW, MINERAL.** See MINERAL TALLOW.

**TALLOW TREE.** Various trees which produce a thick oil or a somewhat resinous substance which may be used for making candles. The tallow tree of Malabar (*Vateria indica*), a tree of the family Dipterocarpaceæ, has leathery leaves, 4 to 10 feet long, and panicles of white fragrant flowers. From incisions in the stem (often 16 feet in circumference) East Indian copal is obtained. Its seeds yield a firm, white, odorless vegetable tallow valued for soap and candle making. The tallow tree of China (*Sapium sebiferum*) belongs to the family Euphorbiaceæ. The nearly hemispherical seed and the capsules yield a white vegetable tallow, which the Chinese obtain by crushing and boiling both capsules and seed and skimming off the fluid fat

The vegetable tallow is exported from China in hard white cakes weighing 50 to 60 pounds each. This tree has been introduced into North America, is cultivated about Charleston and Savannah, and is almost naturalized in the maritime parts of the Carolinas. It is beautiful at the approach of winter, when the leaves become bright red, among which hang the white seeds suspended by threads. The name "tallow tree" is sometimes given to *Aleurites triloba*, a species of candlenut (q.v.). The tallow tree, or butter-and-tallow tree, of Sierra Leone is *Pentadesma butyracea*, of the family Guttiferae, the fruit of which furnishes an oil as butter. See CANDLEBERRY.

**TALLQVIST**, täl'kvist, KNUT L. (1865- ). A Swedish Orientalist, born at Kyrkslätt. Educated at Helsingfors (Ph.D., 1894), at Leipzig, and at Berlin, he became professor of Oriental literature at Helsingfors in 1899. In 1893-95 he traveled in Syria, Palestine, and Egypt. Among his works are: *Die Sprache der Contracte Nabû-Nâ'id's* (1890); *Babylonische Schenkungsbriege* (1891); *Die assyrische Beschränkungsserie Maglû* (1895); *Arabische Sprichwörter und Spiele* (1897); *Ibn Sa'id, Kitâb al-mugrib*, Buch iv (1899); *Neubabylonische Namenbuch* (1905).

**TALLY** (OF., Fr. *taille*, cut, size, figure, tax, from Lat. *talea*, rod, cutting twig). The name given to the notched sticks once used in England for keeping accounts in Exchequer. They were well-seasoned rods of hazel or willow, inscribed on one side with notches indicating the sum for which the tally was an acknowledgment, and on two opposite sides with the same sum in Roman characters, with the name of the payer and the date of the transaction. The tally was cleft through the middle by the deputy chamberlain with knife and mallet, and one-half was retained by the payer as his receipt, while the other was preserved in Exchequer. They accumulated there until 1834, when an Act of Parliament ordered them to be burned.

**TALLYWAG**. See SEA BASS.

**TALMA**, täl'mä', FRANÇOIS JOSEPH (1763-1826). A French tragedian, born in Paris. In 1787 he made his début on the stage of the Comédie Française. Some time afterward in a minor part in the tragedy of *Brutus* he attracted attention by a novelty of costume. It was the fashion for actors to appear in the garb of their own country and even their own time, and Roman senators stalked about the stage attired as Parisian dandies of the eighteenth century. Talma saw the absurdity of the custom and, setting out to reform it, appeared clothed in a Roman toga and with arms bare. His first great triumph was in Chénier's *Charles IX*, produced in 1789. In the division of the Comédie Française (q.v.) which soon followed in the months of Revolutionary confusion, Talma and those who adhered to him went over to the new theatre in the Rue Richelieu, which was for a time known as the Théâtre de la République. There many of his greatest successes were won. Though irritable and often at strife with his fellow actors, he was a great favorite with Napoleon, of whom it was jestingly said that he took lessons of his friend Talma in the art of behaving like an Emperor. Talma was, however, equally well received later by Louis XVIII. Consult his "Quelques réflexions sur Lekain et sur l'art théâtral," prefixed to the *Mémoires de Lekain* (Paris, 1825); *Mémoires de Talma* (ed. by Alex-

ander Dumas, ib., 1849-50); *Lumière, Le Théâtre Français pendant la Révolution, avec plusieurs lettres inédites de Talma* (ib., 1894).

**TALMAGE**, T (THOMAS) DE WITT (1832-1902). An American clergyman and pulpit orator, born at Bound Brook, N. J. After taking a partial course at the University of the City of New York (now New York University) he entered the theological seminary of the Dutch Reformed Church at New Brunswick, N. J., where he graduated in 1856. In the same year he became pastor of the Reformed Church at Belleville, N. J. He filled pastorates in churches of the same denomination at Syracuse, N. Y. (1859-62), and at Philadelphia (1862-69). In 1869 he was called to the pulpit of the Central Presbyterian Church of Brooklyn, N. Y., which, from the new edifice erected in 1870, came to be known as the Tabernacle. During his occupancy of this pastorate, where he remained until 1894, he became widely known as a sensational preacher. The Tabernacle Church, after being twice burned and rebuilt (in 1872 and 1889), was again burned in 1894, after which the church organization ceased to exist. Dr. Talmage preached for a time in the New York Academy of Music and from 1895 to 1899 was associate pastor of the First Presbyterian Church of Washington, D. C. His influence was increased by frequent lecturing tours, both in America and England, and by the publication of his sermons in book form and through syndicates in more than 3600 weekly newspapers in the United States, Canada, and Great Britain. They were also translated and published in a number of foreign languages. He was editor of *The Christian at Work* (1873-76); *The Advance* (1877-78); *Frank Leslie's Sunday Magazine* (1879-89); *The Christian Herald* (1890-1902). Among his more important works were: *The Almond Tree in Blossom* (1870); *Old Wells Dug Out* (1874); *Every Day Religion* (1875); *Woman: Her Powers and Privileges* (1886); *From the Pyramids to the Metropolis* (1892); *From Manger to Throne* (1894); *The Earth Girdled* (1895); *The Pathway of Life* (1895). Dr. Talmage's sermons were written in a popular vein and were characterized by extravagant statements and fantastic figures of speech. Consult: C. F. Adams, *Life and Sermons of T. De W. Talmage* (Chicago, 1902); C. E. Banks, *Life and Works of T. De W. Talmage* (New York, 1902); W. C. Wilkinson, in *Modern Masters of Pulpit Discourse* (ib., 1905).

**TALMUD** (Aram. *talmūd*, instruction; connected with Heb. *lāmad*, to learn). The name given to the comprehensive compilation of laws and ceremonial regulations pertaining to rabbinical Judaism together with the elaborate discussion of those laws and regulations. As already implied in this definition, the Talmud consists of two divisions, which in the compilation are kept distinct: (1) the laws and regulations which are technically comprised under the designation *Mishnā* (lit. teaching, then used concretely for "the law," as that which is taught or which is the outcome of teaching); (2) the discussion and elaboration of the laws, comprised under the term *Ġemārā* (lit., supplement, completion, and then also in the sense of tradition, doctrine). The language of the Mishna is Hebrew; that of the Gemara, Palestinian or Babylonian Aramaic.

Of these two divisions, the compilation of the Mishna comes first in the order of time and also

in importance. In its present form it consists of six main divisions known as *Sedarim*, comprising 63 treatises, or *Massektōth*. This comprehensive compilation, which is attributed to Rabbi Jehuda ha-Nasi (c. 219 A.D.), represents the culmination of an intellectual and religious process that may be said to date from the acceptance of the Law as the supreme and sole standard of religious observances and secular regulations. The observer of the Law was the only type of the faithful Jew possible under this conception of religious duty. Such a principle necessarily led to the study of the Law as the highest vocation of the individual. The Law could not be observed unless it was known and thoroughly understood, and generations of scholars arose who strove to determine the exact meaning of the enactments in the codes and to account for numerous existing practices not specifically recorded in them, by deduction from principles underlying the code itself. The attempts to deduce the established religious practices and the constantly growing ceremonial details from the Law itself resulted naturally in the formation of smaller and larger collections, which may have served either as notes for the pupils or as guides for the teachers, and despite a certain opposition that always manifested itself against committing to writing the large body of oral tradition, which, according to the theory of rabbinic theology, was revealed simultaneously with the written Law at Sinai, it was inevitable, if the practices established by or based upon this oral tradition were to maintain their hold as ingredient parts of Judaism, that they should be given a fixed form equally with the written Law. We have direct evidence for the existence of Mishnaic compilations prior to the days of Rabbi Jehuda ha-Nasi, but the general acceptance which his compilation met naturally drove the earlier (and probably more incomplete) ones out of the field. Traces of these are to be found in the Talmud and in Midrashim, where enactments and observations are referred to which differ from those found in the Mishna; they are designated as the *Bārāithā* (i.e., outside). A separate collection of this kind is known as the *Tōsephthā* (addition), which, however, partakes of the character of the Gemara.

Passing on to the supplement to the Mishna, its rise represents the natural continuation of the process which led to the Mishna. In the course of several centuries there was a large accumulation of material that could only be preserved by being committed to writing. The combination of the Mishna with the Gemara forms the Talmud proper, and for the Babylonian schools the first authoritative compilation of the discussions of the several generations was made by Rab Ashi, the head of the school at Surā, who flourished from 375 to 427; but additions were made by later authorities, such as Rab-Abina, and the final touches were given to it about the first half of the sixth century. In a certain sense, however, the Gemara was never finished, for of the 63 treatises of the Mishna 26 have no Gemara. The Palestinian schools also compiled their discussions, and in this compilation the influence of Rabbi Johanan (180-279), head of the school at Tiberias, is paramount, though the redaction of the Palestinian Talmud—the work of a series of authorities—did not take place until the fourth century, while additions continued to be made to it in the fifth century, Jose ben Abin taking an im-

portant part in the final redaction. Considerable portions of this Palestinian Talmud are lost. In fact, the Mishna of only the first four Sedarim or divisions has been preserved, and a portion of one treatise in the sixth division. In the second division the Gemara is not complete, four chapters of one treatise being wanting, and likewise in the fifth division the Gemara is lacking to the last chapter of one treatise and to two other treatises. That the Palestinian Talmud once existed in a more complete form is certain, and it is more than likely that there was a Gemara to most of the treatises of the entire six divisions. The loss of such a considerable portion is due in part to the almost constantly disturbed conditions that prevailed in Palestine, and in part to the subsequent neglect of the Palestinian Talmud, which never acquired the authority that came to be enjoyed by the Babylonian compilation. The Babylonian Gemara in fact drove its rival entirely out of the field, and as a consequence the Babylonian Talmud became the main factor in the history and development of Judaism.

To characterize and convey an idea of the contents of the Mishna is a comparatively simple matter, but it is almost an impossible task to indicate the heterogeneous character of the Gemara, more particularly of the Babylonian Talmud. The discussions on the Mishna led the rabbis and their pupils far away from the subject, at times, indeed, a section coming to a close without a return to the starting point. In the course of these digressions, anecdotes, bits of historical gossip, folklore, the popular science of the day, and mathematical calculations are intermixed with sober and playful exegesis of the Old Testament by the application of a series of hermeneutical principles evolved in the schools of Palestine and Babylonia. Sophistry and hairsplitting dialectics are suddenly interrupted by charming parables and poetic allegories. The Gemara is a veritable encyclopædia of rabbinical knowledge, and only the lack of system prevents the justifiable application of that term to this remarkable compilation. To distinguish the purely legal from the extraneous material, a division is commonly made into Halacha (lit., norm) and Haggada (lit., tale).

The history of the Talmud is the history of Judaism from about the beginning of our era to the dawn of the nineteenth century. In that history we may distinguish the following periods: 1. To the completion of the Mishna, during which time the rabbis bear the name of *Tannaim* (teachers); five generations are enumerated. 2. The growth of the Gemara, the rabbis of this second period being known as *Amoraim* (speakers), comprising seven generations. 3. To the completion of the Talmud, the rabbis of this period being distinguished as *Saboraim* (examiners). 4. To the struggle in the ninth and tenth centuries between the Karaites and the adherents of the Talmud known as the Rabbanites, marked by the labors of Saadia (q.v.). 5. The adjustment of Talmudical Judaism to the prevailing form of Aristotelianism, which arose under the influence of Islamic theology. This period extends well into the thirteenth century and is dominated by the influence of Maimonides and the Spanish school of Jewish thinkers. It led eventually, after a long conflict between the adherents and opponents of Maimonides' attempt to codify the Talmudical enactments and regulations in syste-

matic form, to the compilations of the codes of Joseph Karo (born 1487), known as the *Shulchan Aruch* (spread table), which became the standard guide implicitly followed by orthodox Jews to the present time and may be regarded as marking a sixth and final period.

In the course of the last two periods the study of the Talmud spread gradually into southern Europe and thence made its way into Germany, Galicia, Hungary, and Russia. Commentators arose who devoted themselves to the interpretation of the Gemara, much as the Amoraim and Saboraim elaborated the Mishna, and super-commentaries were added to these commentaries. The most notable of the Talmudical commentators was Rabbi Solomon Yishaki (or Isaac), known as Rashi (q.v.), whose work, almost invariably added to the Talmudic text, is still used as the basis of Talmudical study. A school of Talmudists arose in Germany and France during the twelfth and thirteenth centuries known as *Tosaphists* (supplementers), whose comments are likewise written on the margins of the Talmud—a method that follows the example of the Mohammedan theologians. Other commentators of more recent date whose works acquired a high degree of authority were Solomon Luria (died 1573), Elijah Wilna (died 1797), and Akiba Eger (died 1837). From Germany, which remained for several centuries the centre of Talmudical study, that centre gradually shifted to the east of Europe, and at the present time the traditional methods of Talmudical study are still carried on with vigor in Galicia and Russia, while the centre of the scientific study of the Talmud based on adequate philological acquirements and the application of proper historical principles may be said to be Germany, whence the study is spreading into France, England, and the United States, as the value of the Talmud for the student of language, of history, and of religion is coming to be recognized. Christian theologians are also beginning to take it up, and notable contributions have been made by some of these. See GEMARA; HAGGADA; HALACHA; MISHNA.

**Bibliography.** A thoroughly critical edition of the entire Talmud is still a desideratum. On the recent editions of the Mishna text, see MISHNA. The great Munich Codex of the Babylonian Talmud was published by M. Altschürer and J. Long Lichtenfels, in *Orbis Antiquitatum* I (Berlin, 1908) and more correctly by H. L. Strack, *Talmud Babylonicum Codicis Hebraici Monacensis* 95, I (Berlin, 1912). The text is also printed by Lazarus Goldschmidt, in *Der Babylonische Talmud*, i-iii, v-vii (Leipzig, 1897-1912). The variant readings gathered from manuscripts and older editions have been published by Raphael Rabinovitch, *Sefer Dikduke Sopherim* (15 vols., Munich, 1868-86). Of translations of the Talmud into modern languages, it will be sufficient to mention here the French translation of the Palestinian Talmud by Moïse Schwab (11 vols., Paris, 1871-89; vol. i, 2d ed., 1890); the German translation of the Babylonian Talmud by L. Goldschmidt (Berlin and Leipzig, 1897-1912); and the English translation of the Babylonian Talmud by Rodkinson (New York, 1896 et seq.). An English translation of 18 treatises of the Mishna by J. Barclay was published in London in 1878. A Latin translation of the Tosephta will be found in Blaisio Ugolino, *Thesaurus Antiquitatum*, vols. xvii-xx (Venice, 1755-57). Of general works

on the Talmud, the following may be mentioned. I. Hamburger, *Realencyklopädie für Bibel und Talmud* (Leipzig, 1886); F. Weber, *Jüdische Theologie auf Grund des Talmud* (ib., 1897). Of monographs or articles on the Talmud, consult: Emmanuel Deutsch, "The Talmud," in *Literary Remains*, republished by the American Jewish Publication Society (Philadelphia, 1897); Arsène Darmesteter, *The Talmud* (Eng. trans., ib., 1897); A. Bernfeld, *Der Talmud: sein Wesen, seine Bedeutung, und seine Geschichte* (Berlin, 1900); Hermann Strack, *Einleitung in den Talmud* (5th ed., Leipzig, 1911), which contains in concise form the contents of the Talmud, editions, history, and a valuable bibliography. Consult also: Mielziner, *Introduction to the Talmud* (2d ed., New York, 1902); Rodkinson, *History of the Talmud* (ib., 1903); W. Bacher, "Talmud," in *The Jewish Encyclopedia* (ib., 1906); E. Bischoff, *Die Entstehung des Talmuds* (Leipzig, 1910); M. Brann, *Geschichte der Juden und ihre Literatur* (3d ed., ib., 1910); A. Fiebig, "Mishna, Talmud, und Midrasch," in *Die Religion in Geschichte und Gegenwart* (Tübingen, 1913).

**TALON**, tā'lōn', JEAN BAPTISTE (1625-91). A French official in Canada, born in Picardy. He entered the civil service and, after serving in subordinate capacities in France, was appointed in 1663 intendant of justice, police, and finance in Canada, Acadia, and the other French possessions in North America. Talon built ships, began trade with the West Indies, and built a brewery to lessen the consumption of brandy. Exploring parties were sent to Hudson Bay and to the country of the Upper Lakes, and the purchase or seizure of New York was urged. In 1668 he returned to France on account of failing health, but returned in 1670 and remained until 1672. Later three of his seigniories were erected into baronies, and he assumed the title of Comte d'Orsainville. His *Mémoire à Sa Majesté sur l'état présent du Canada* (1667) is a valuable original source of information.

**TALTAL**, tál-tál'. A town of the Province of Antofagasta, Chile, on the Bay of Taltal, Pacific Ocean, 527 miles north of Valparaíso (Map: Chile, E 3). It is the terminus of the railway of some 95 miles running to the mining town of Cachinal and is the point of export for the nitre beds and silver and copper mines of the deserts of Atacama (q.v.). Taltal was founded about 1855. Pop., 1903, 6720.

**TALUS** (Lat., heel). The heap of fragments that accumulates at the base of cliffs and mountain slopes. Weathering is the most important process in the production of such masses, which tend to move slowly downward until they come within reach of the valley stream. The inclination of the surface of the talus varies with the size of the fragments, but it rarely exceeds an angle of 35° with the horizontal.

**TAL/VJ.** See ROBINSON, THERESE ALBERTINE LUISE.

**TAMAGNO**, tà-mān'yō, FRANCESCO (1851-1905). An Italian operatic tenor, born in Turin. He made his debut in Palermo in 1873 in *Un Ballo in Maschera*, and for 30 years was famous throughout Italy and Europe in such operas as *Otello* (the chief part of which he created in Milan in 1887), *Il Trovatore*, *Aida*, etc. He made several visits to the United States, the first in 1893. In 1902 he retired from the stage. He died at Varese.

**TAMANACA**, tā'mā-nū'kà. A tribe of Cari-

ban stock (q.v.) who formerly lived on the Cuchivero River, a southern affluent of the Orinoco, central Venezuela. They were at one time one of the most powerful tribes of Venezuela, and were Christianized and gathered into mission villages by the Spanish missionaries before the year 1780, but by the incessant attacks of the savage Carib (q.v.) they were so wasted that before the year 1840 the name had disappeared, and they are supposed to be entirely extinct.

**TAMAN'DUA.** See ANT-EATER.

**TAMANOIR,** tā'mā'nwair'. See ANT-EATER.

**TAMAQUA,** tā-mq'kwā. A borough in Schuylkill Co., Pa., 17 miles northeast of Pottsville, on the Little Schuylkill River and on the Philadelphia and Reading, the Lehigh and New England, and the Central of New Jersey railroads (Map: Pennsylvania, J 5). It is known for its extensive coal-mining interests. The leading manufactures are foundry and machine-shop products, stoves, powder, flour, hosiery, silks, shoes, furniture, shirts and shirt waists, knit goods, and beer. The city contains a State hospital. Tamaqua was settled in 1799 and was incorporated as a borough in 1833. Pop., 1900, 7,967; 1910, 9,462; 1915, 10,618; 1920, 12,363.

**TAMAR,** tā'mār. A picturesque river which rises in the north of Cornwall, England, and after a southeast course of 60 miles enters the English Channel by its estuary the Hamoaze and Plymouth Sound (Map: England, B 6). It forms the boundary of the counties of Cornwall and Devon for 45 miles and is navigable as far as Launceston. Consult Bray, *The Tamar and the Tavy* (London, 1879).

**TAM'ARACK** (North American Indian name), *Larix laricina*. An American timber tree, 30 to 90 feet tall, common in swamps. Its hard resinous wood is valued for posts, poles, ties, etc. It is less ornamental than its close relative, the European larch, which is more frequently planted. See LARCH.

**TAMARAO,** tā'mā-rā'ō (native name). A small, sturdily built native buffalo (*Bos mindorensis*) of the Philippines. It is about 3½ feet high at the shoulders, is clothed with thick brown hair, and has short, triangular, massive horns, which have a lyrate curvature upward from the face. Cf. BUFFALO.

**TAM'ARIN.** See MARMOSET; NEGRO MONKEY.

TAMARIND AND FRUIT.

**TAM'ARIND** (ML. *tamarindus*, from Ar. *tamr Hindī*, *tamr al-Hind*, date of India), *Tamarindus indica*. A beautiful spreading tree, of

the family Leguminosae, a native of India, very generally cultivated in warm climates. It bears brown, many-seeded pods about 6 inches long and ¾ of an inch thick, filled with acidulous, reddish-brown pulp which is exported in jam-like masses to Europe. Tamarinds are generally preserved by pouring hot sirup on the ripe pulp; a better method is to put alternate layers of tamarinds and sugar in a stone jar, the color and taste being thus more like the fresh pulp. The wood of the tamarind and especially of its roots is extremely hard and, though worked with difficulty, is valued for cabinetwork. There are several species of *Dialium*, known as velvet tamarind, closely related to *Tamarindus*, that yield a similar pulp. Tamarind pulp is used in India as a cooling food, for sherbets, etc. Tamarind trees are grown to some extent in Florida, but were not satisfactory when tested at Berkeley, Cal.

**TAMARISK** (Lat. *tamariscus*, *tamarix*, *tamarice*, *tamarisk*; perhaps connected with Skt. *tamālaka*, *tamāla*, a sort of tree with dark bark, *tamas*, darkness), *Tamarix*. A genus of plants of the family Tamaricaceae. The common tamarisk (*Tamarix gallica*) grows in sandy places in the Mediterranean region and is often planted for ornament in Europe and the United States. It sometimes attains a height of 30 feet. The twigs were once in repute as a tonic. The Oriental tamarisk (*Tamarix articulata*) is one of the few indigenous trees in the Arabian and African deserts. It is called atle or ethel. Its wood is used for fuel and for economical purposes. The galls found on some East Indian species are valued in dyeing. *Tamarix mannifera*, perhaps a variety of *Tamarix gallica*, owing to the punctures of an insect, yields Mount Sinai manna. The German tamarisk (*Myricaria germanica*) belongs to another genus of this order.

**TAMASHEK,** tā'mā-shēk. The name applied to the Berber and Tuareg languages of Mauretania and the Sahara. It occurs in various dialectic forms as Tamahāg, Tahahūg, and Tama-zigt. The last form (Tama-zig-t) survives in the Amzigh or Imazighen (q.v.), the common name of Mauretanian Berbers and thought to be identical with the Maxyes of Herodotus. Consult: Freeman, *Grammatical Sketch of the Tama-hug or Towarek Language* (London, 1862); Hanoteau, *Essai de grammaire de la langue tamacheke* (2d ed., Algiers, 1896); Kaoui, *Dictionnaire français-tamâheq* (ib., 1894); id., *Dictionnaire pratique tamâheq-français* (ib., 1900).

**TAMATAVE,** tā'mā-tā'vā. The most important seaport of Madagascar. It is on the east coast, in lat. 18° 10' S., on a small peninsula (Map: Africa, K 6). It is fortified and has a good roadstead, owing to the outlying coral reefs, but the facilities are not superior for loading and unloading vessels. South of the

COMMON TAMARISK.

TAMARACK AND LARCH

1. TAMARACK (*Larix Americana*).

2. SPRAY WITH CONES OF EUROPEAN LARCH.

3. EUROPEAN LARCH (*Larix Europaea*).

city is a series of lagoons which have been connected by canals and thus add to the transportation advantages of the town. In 1913, 10,086 vessels of 1,668,865 tons entered the port. (See MADAGASCAR.) A railroad at present connects Tamatave with the neighboring Ivandro. Pop., 1911, 8761. There are a number of Europeans.

**TAMAULIPAS**, tã'mou-lé'pás. A maritime state of Mexico (Map: Mexico, K 6). Area, 30,826 square miles. The coast is flat, sandy, lined with lagoons and marshes, and but sparsely inhabited. The northern part is occupied by plains, while the southern and central portions are mountainous. Tamaulipas is watered by several large rivers, of which the largest are the Río Grande and Pánuco, forming respectively the north and south boundaries. The climate is temperate and healthful in the interior and hot and unhealthful on the coast. Agriculture is the principal industry, but is hindered by lack of irrigation facilities. Grazing is carried on extensively. The chief exports are hides and skins, live stock, some fruits, and rubber. There are three railroad lines in the state. The Mexican Free Zone, in which imports are liable to only 10 per cent of ordinary duties, was first established by Tamaulipas in 1858. Pop., 1910, 249,641. Capital, Victoria (q.v.).

**TAMAYO Y BAUS**, tã-mã'yó 'ë bous', MANUEL (1829-98). A Spanish dramatist. He was born in Madrid of parents both of whose families were distinguished in the annals of the stage, and his early life was passed in traveling about the provinces with the company of which his parents were members. He was a lifelong friend of Manuel Cañete (q.v.). He was elected (1853) to the Spanish Royal Academy, of which he became permanent secretary in 1874. From 1884 till his death he was director of the National Library and chief of the board of archivists, librarians, and antiquarians. When Tamayo y Baus was only 11 years old, he made a translation or adaptation of *Geneviève de Brabant* which was successfully staged, with his mother in the title rôle, at Granada. His dramaturgic manifesto, *Truth as the Fountain of Beauty in Dramatic Literature* (1858), was widely influential. His most important plays are: *La Locura de Amor* (1855), dealing with the madness of Juana la Loca, the daughter of Ferdinand and Isabella; *Lances de Honor* (1863), treating of the evil of dueling; *Un Drama Nuevo* (1867), a perfect example of the incorporation of a play within a play. By most critics *Un Drama Nuevo* is considered not only Tamayo's masterpiece, but also one of the great plays of all literature. It was translated into English by J. D. Fitz-Gerald and T. H. Guild as *A New Drama* (New York, 1915). Consult: Manuel Tamayo y Baus, *Obras* (4 vols., Madrid, 1898-1900); Emilio Cotarelo y Mori, *Historia literaria*, vol. i (ib., 1901); Boris de Tannenberg, *L'Espagne littéraire, première série* (Paris, 1903); Narciso Sicars y Salvadó, *D. Manuel Tamayo y Baus* (Barcelona, 1906).

**TAMBÓBONG**, tã-m-bó'bóng. A suburb of Manila, Philippines, situated about 3 miles north of the capital, in the Province of Rizal. Pop., 1903, 20,136.

**TAMBOUR**, tã'm'bôor (Fr., drum). In fortification a small traverse to prevent the enfilade of a trench, or in other words, a small work projecting from the main line of a fortification, often in the form of a redan or a lunette with

a salient angle of about 60°. In older schemes of fortification the tambour usually consisted of a timber structure or stockade with loopholes which could protect the gateway of an approaching road, or afford a flanking fire on a bridge. In formal schemes of fortification, the tambour on the covered way would be used to close the entrance from the glacis. See FORTIFICATION.

**TAMBOURIN**, tã'n'bôor'ân' (Fr. *tambourine*, dim. of *tambour*, drum, tabor). An ancient, lively dance of Provence, in  $\frac{3}{4}$  time. It was originally accompanied by a flute and a tambour (drum); hence the name.

**TAMBOURINE**, tã'm'bu-rên'. An ancient instrument of the drum type. It is composed of a piece of parchment, stretched on the top of a hoop furnished with pairs of small metal plates, and is sounded by the hands, fingers, or elbow.

**TAMBOV**, tã'm-bôf'. A government of central Russia (Map: Russia, F 4). Area, 25,710 square miles. Its surface is mostly flat, in the basins of the Oka and the Don, and intersected by numerous river valleys. The region is watered principally by the Voronezh and the Khoper (tributaries of the Don) and by the Moksha and the Tsna (tributaries of the Oka). Iron is found near Lipetsk, but it is little exploited. Tambov is one of the most fertile governments of Russia, and its southern and larger part is covered with a thick layer of black soil. Rye and oats are the principal cereals. Flax, tobacco, and sugar beets are also produced on an increasing scale. The principal manufactured products are spirits, cloth, beet sugar, flour, and tobacco. The annual value of the output often exceeds \$12,000,000. Pop., 1912, 3,473,000.

**TAMBOV**. The capital of the Government of Tambov, Russia, in a low region on the Tsna River, about 300 miles southeast of Moscow (Map: Russia, F 4). Pop., 1910, 60,729. The city was founded in 1636 as a fortress against the inroads of the Tatars from the south.

**TAM'BURLAINE, THE GREAT**. A tragedy in blank verse, by Christopher Marlowe, acted in 1587 and licensed for publication on Aug. 14, 1590. Its principal source is a translation of Petro Mexia's *Silva de Varia Leccion*, made by Thomas Fortesque, and published under the title of *The Foreste* in 1571.

**TAM'ERLANE**. See TIMUR.

**TAMERLANE**. 1. A tragedy by Rowe, produced at Lincoln's Inn Fields in 1702 and adapted (1724) for the operatic stage to the music of Handel. Owing to its political significance, the play came to be produced annually at the Drury Lane on November 5. 2. A poem by Edgar Allan Poe which gave its name to his volume of verse published in 1827.

**TAMETOMO**, tã'm-e-tô'mô. Japan's most famous archer. He belonged to the great Minamoto family and shared its misfortunes in the middle of the twelfth century. He is credited with many feats of strength and skill. He sent an arrow through the body of one man and wounded a second who stood behind him. He shot an arrow through the helmet of his own brother without hurting him. Being taken prisoner and a sinew of his arm having been extracted by his foes, he came nevertheless to shoot a stronger bow and sank a boat by shooting an arrow through its bows. The accounts of his end are contradictory. After sinking the boat he fired his house and committed suicide, or he fled to Ryukyu (Luchu) and became its King, the first of the historic line.

**TAMILS.** A Dravidian people of southern Hindustan and northern Ceylon, who number more than 18,000,000. They are, perhaps, the most important of the civilized Dravidian people of India. The Klings of the seaports of Farther India and certain parts of Malaysia are Tamils, who have emigrated temporarily or permanently from their native land.

The Tamil language is the most important and archaic of the Dravidian languages. It is spoken in the northern half of Ceylon, and the territory between Cape Comorin and Pulicat, north of Madras, extending inland about half-way across India. Tamil is divided into the widely different Old or Son Tamil and Modern or Kodun Tamil. It has nine cases, two numbers, and in gender distinguishes between high caste (men, gods, spirits, etc.) and low caste (animals, inanimate things, and abstract ideas). The verb is formed by suffixing the personal pronouns to a predicative verb stem. The same base, therefore, when case suffixes are added, serves as a noun and, when the pronouns are affixed, as a verb. Moods are altogether lacking. In its vocabulary Tamil is exceedingly rich, especially in compounds and synonyms. The alphabet is based on one of the old forms of the Sanskrit Devanagari (q.v.) script. Tamil literature is abundant and important. An outline is given under DRAVIDIANS.

**Bibliography.** Rottler, *A Dictionary of Tamil and English* (Madras, 1834-41) and the Tamil and English dictionaries of Winslow (ib., 1862), and Visvanatha Pillai (ib., 2d ed., 1897); Mateer, *Native Life in Travancore* (London, 1883); Rhenius, *Grammar of the Tamil Language* (4th ed., Madras, 1888); *Tamil Antiquary* (ib., 1903 et seq.); Vinson, *Manuel de la langue Tamoule* (Paris, 1903); Pope, *First Lessons in Tamil* (7th ed., Oxford, 1904); id., *Handbook of the Ordinary Dialect of the Tamil Language* (ib., 1905); *Publications of the India Linguistic Survey*, vol. iv (Calcutta, 1906); Thurston, *Castes and Tribes of Southern India* (Madras, 1909); Caldwell, *Comparative Grammar of the Dravidian or South Indian Family of Languages* (3d ed., London, 1913).

**TAMING OF THE SHREW, THE.** A comedy by Shakespeare, written before 1596, produced in 1603. It is adapted from an earlier play entitled *The Taming of a Shrew*, of questionable authorship, produced in 1594. The story of Bianca is taken from Ariosto's *I suppositi* through Gascoigne's *Supposes*, a play of 1566. The "taming" comes from an old and widespread story found in the *Arabian Nights* and in Straparola.

**TAMISE, tá'méz'.** A town in the Province of East Flanders, Belgium, 11 miles southwest of Antwerp, on the Scheldt and on the railway from Mechlin to St. Nicholas. Its chief manufactures are cotton and woolen fabrics, laces, soap, and wooden shoes; boat building and jute and flax spinning are carried on. Pop., 1900, 12,463; 1910, 13,306.

**TAMMANY HALL.** The name applied (1) to a powerful political organization in New York City, (2) to the building which serves as that organization's headquarters, and (3) sometimes incorrectly to the society from which the organization leases the building. The name is adapted from that of an Indian chief, Tamanend, of the Lenni Lenape or Delaware tribe, who was famous for his virtues and his wisdom, but about whom little is definitely known. His

name appears on deeds for tracts of land, dated June 23, 1683, and July 5, 1697; and according to tradition he died about 1740 and was buried in New Britain Township, Bucks Co., Pa. Before and during the Revolutionary War patriotic societies, akin in spirit to the Sons of Liberty, with Tamanend as their patron saint were organized in imitation of and opposition to such Tory societies as St. Andrew's Society, St. David's Society, St. George's Society, and the Friendly Sons of St. Patrick. In Philadelphia the Sons of King (later St.) Tammany met almost every year from 1772 to 1791, and later, in 1795, a short-lived branch of the New York society was established there. Similar societies of St. Tammany had a brief existence in Providence, Brooklyn, and Lexington. See SECRET SOCIETIES.

On May 12, 1789, William Mooney, an upholsterer and ex-soldier, who previously had been active as one of the Sons of Liberty, founded in New York, ostensibly as a patriotic and social organization, the secret Society of St. Tammany or Columbian Order, which in 1805 was regularly incorporated as a fraternal aid association. The ritual and organization of an Iroquois lodge were followed more or less closely by the founders, the society being divided into 13 tribes, each of which had its separate totem, the year being divided into four seasons, each month, or rather moon, being called by some distinguishing characteristic, and the officers, annually elected, being known as the grand sachem, sachems, the sagamore, or master of ceremonies, scribe or secretary, and the wiskinskie or door-keeper. The place of meeting was called the Wigwam, a name often used to mean Tammany Hall itself. It was the custom to confer the honorary title of Great Grand Sachem upon the Presidents of the United States, and, from Washington to Jackson, all accepted. Until their abandonment in 1813, it was the practice of Tammany Society to have picturesque ceremonies according to Indian custom. In 1811 the society built its first hall, at the corner of Frankfort Street and Park Row, in 1867 moved to Fourteenth Street, and in 1915 it decided again to change locations, selecting a site farther uptown. The political organization is nominally distinct from the society.

Though the society was ostensibly organized for patriotic, social, and benevolent purposes, it early took an active interest in politics and soon came to stand distinctively for democracy and decentralization, identifying itself definitely (in 1798) with the Democratic-Republicans as opposed to the Federalists. Though never an officer, Aaron Burr is supposed to have given the society its first training in the devious ways of practical politics. He was assisted by Matthew L. Davis, who carried out his orders. The remarkable organization as a political machine was effected or at least perfected under Martin Van Buren during the contest within Tammany Hall between the friends of Jackson and those of Adams. In 1800 the society first took an active part in a political campaign, being instrumental in carrying New York for Jefferson. From that time to the present Tammany has generally professed to be the local representative of the National Democratic party and has exerted a powerful influence on the political history of the State and a preponderating influence on the political history of the city. Generally the organization has been bitterly assailed by rival factions of the Demo-

cratic party, and on at least one occasion, in 1878, under Kelley, it bolted the party's regular State ticket, but for the most part it has controlled a vast majority of the Democratic voters of the city. After 1834, when the mayoralty first became elective, it devoted its attention primarily to securing control of the city government and from 1834 to 1913 succeeded in electing fully two-thirds of the mayors. Gradually its organization became more and more perfected, and the inrush of immigrants after about 1840 added enormously to its strength, for Tammany succeeded in securing the adhesion of an immense majority of the foreign-born citizens. In order to secure proper compactness and discipline within the organization, great power was necessarily thrown into the hands of a few individuals, and in the history of Tammany many of its officers are alleged to have succumbed to the temptations which such power has brought. From an early period charges of corruption, speculation, and blackmail were made against Tammany leaders by their political opponents, and Tammany often retaliated with similar charges against the opposition, as in 1839 against the Whigs. The climax was reached in 1869-71, when Tweed and his associates were proved to have robbed the city of untold millions. (See TWEED, WILLIAM M.) Damaging disclosures concerning the methods of Tammany were also made during the investigations conducted respectively by the State Committee on Cities, headed by J. Sloat Fassett, in 1890, the special committee of the State Senate, headed by Clarence Lexow, in 1894, and the special committee of the State Assembly, headed by Robert Mazet, in 1899.

Tweed was the first to exercise over Tammany the powers of the modern boss. After the exposure of his colossal frauds Tammany was severely criticized. On a platform of reform and regeneration it was reorganized by John Kelly (q.v.), who caused some of the most prominent of Tweed's prosecutors—men like Tilden, Charles O'Connor, Horatio Seymour, and August Belmont—to be chosen as officers, while he, by perfecting the machinery of the organization, gained almost entire control. At his death, in 1886, he was succeeded by Richard Croker (q.v.), who, however, did not exercise the powers of a boss until 1888, and who in 1901 retired. Lewis Nixon (q.v.) was then nominally the leader for several months. Tweed, Kelly, Croker, and Nixon had each been chairman of the finance committee; this committee was reorganized in 1903, after the policy of Tammany had been shaped for a time by a triumvirate, and Charles F. Murphy (q.v.) was chosen leader. A man of remarkable political talents, Murphy soon gained for himself virtually absolute power. In 1912, after he had secured the elections of McClellan and Gaynor, he was made one of the issues in the national campaign. The whole Tammany system was sharply criticized. The control of Tammany in State Democratic politics, despite occasional rebuffs, has been well-nigh absolute.

In organization Tammany is highly centralized, the power resting ultimately in the hands of one man or of a relatively small number of men. There is a captain for each election district in the city, and a district leader for each Assembly district. The executive committee of the organization is generally made up of these various district leaders; while in addition each

district elects a certain number of men to the so-called General Committee, in which ostensibly the power rests, and in whose name the lease of the building known as Tammany Hall is held. The men elected by each district to the General Committee, whose membership is somewhat in excess of 5000, form the General Committee for that district and are presided over by the district leader. The General Committee has standing subcommittees on finance, printing, naturalization, correspondence, and organization.

The power of Tammany is traceable, however, to something more than mere machine organization. It makes a systematic appeal for the votes of the lower classes and accomplishes its purpose by numerous acts of real charity; by gratifying the social instincts of the tenement dweller, the district leaders giving at their own expense frequent dances, chowder parties, picnics, and excursions; by bailing unfortunates out of jail; by systematically ingratiating itself with the vast numbers of immigrants; by securing work for the unemployed; by an extensive and generally astute use of patronage (when Tammany is in power); and apparently by the application of pressure and various acts of virtual intimidation. It also gains votes by virtue of its position as the representative in New York of the Democratic party, and, by the lax enforcement of sumptuary laws when in power, it wins the support of those voters who on principle or through motives of self-interest oppose such laws. In the midst of revelations of fraud and corruption such as in the case of Tweed, and of defeat, as in 1913 by the Fusionists, Tammany has evinced a wonderful vitality. By nominating for mayor such men as Have-meyer, Hoffman, Hewitt, and Gaynor, and by denouncing the corruption and aristocratic tendencies of the opposition, it has recovered power. According to its own standards Tammany Hall has been an efficient organ for government. Arrayed against it are the members of the Republican party, a large majority of the cultured and well-to-do classes, and large numbers, representing various classes, who are convinced that Tammany government means a government of blackmail, of fostered vice, of police corruption, and, if not of outright dishonesty in all respects, at least of general wastefulness and inefficiency.

**TAMMANY SOCIETIES.** See TAMMANY HALL; SECRET SOCIETIES.

**TAMMERFORS,** tām'mēr-fōrs' (Finnish

*Tampere*). The principal manufacturing city of Finland, Russia, situated in the Government of Tavastehus, close to the falls of Tampereenkoski and 125 miles northwest of Helsingfors by rail (Map: Russia, B 2). It is a modern town with extensive cotton, paper, saw and iron mills, and various other manufacturing establishments (including locomotive works and shipyards), whose motor power is supplied chiefly by the near-by rapids. Its principal import is cotton, of which 7,687,100 pounds were imported in 1913. The town was founded in 1779, while its industrial development dates from the beginning of the nineteenth century. Pop., 1912, 45,791.

**TAMMUZ.** A deity of Sumerian origin worshipped in Babylonia and also, according to Ezekiel viii. 14, in the temple at Jerusalem, where women wept for Tammuz. The meaning of the Sumerian name, Tamuzu, or Duuzi-Duzi, seems to be *aplu kenu*, true son. He is represented as a son of Ea, and probably had his original home at Eridu. At first he was apparently an agricultural deity. He is mentioned in the inscriptions of Gudea of Lagash, in the Adapa-myth and in the Gilgamesh Epic. In the developed Babylonian mythology he became the symbol of the decay of vegetation after the close of the summer season, pictured as slain by the goddess Ishtar after she has secured him as her husband. The death of Tammuz gave rise in Babylonia to the mourning ceremonies described by Ezekiel, and from Babylonia as a centre the cult spread to the West. There was a relation of Tammuz to the boar already in Babylonia. Among the Canaanites Tammuz was known as *Adonis*, the lord, and this name was given by the Greeks as *Adonis* (q.v.). Among the Phœnicians the chief temple and worship of Adonis was at Byblus (or Gebal), and from Phœnicia the Adonis cult was carried to Cyprus and Greece, where he was connected with Aphrodite. His festivals were partly the expressions of joy, partly of mourning. In the latter the women gave themselves up to the most unmitigated grief over the lost Adonis, shaved off their hair, and sacrificed their chastity in his temples. The days of mourning were completed by a solemn burial of an image of the god. This period was followed by a succession of festive and joyful days in honor of the resurrection of Adonis. The river Adonis (Nahr Ibrahim), which once a year ran purple to the sea from the Lebanon, was supposed to be tinged by the blood of the god; and a vessel sent off from Alexandria, and carried by the tide to Byblus, used to inform the mourners by letter that he had been found again. These feasts were celebrated during the summer solstice. The fourth month in the Babylonian calendar, known as Tammuz and adopted by the Hebrews, preserves the name of the god and furnishes a valuable testimony as to the time when his festival was celebrated, since the Babylonian year began in the spring. Adonis of Byblus was identified with Osiris, Athtar, Dusares, Attis, and other gods. This was no doubt facilitated by the similarity of mythopoetic thought in different peoples. Our information concerning the Tammuz Adonis cult comes partly from Lucian's *De dea Syra*, partly from the monuments on the Adonis River in the Lebanon. Consult: W. R. Smith, *Religion of the Semites* (London, 1894); H. Zimmern in E. Schrader, *Die Keilinschriften und das Alte Testament* (3d ed., Berlin, 1902);

Baudissin, *Adonis und Eshmun* (Leipzig, 1911); S. Langdon, *Tammuz and Ishtar* (Oxford, 1914); J. E. Frazer, *Adonis, Attis, Osiris* (3d ed., London, 1914); G. A. Boston, "Tammuz and Osiris" in *Journal of The American Oriental Society* (New Haven, 1915).

**TAM O' SHANTER.** One of the best-known poems of Robert Burns, based on the popular belief that no evil spirit can pass the middle of a running stream. The hero is pursued by witches for disturbing their dance at Alloway Kirk, and succeeds in crossing the river Doon in safety.

**TAMPA.** A city, port of entry, and the county seat of Hillsboro Co., Fla., 212 miles south by west of Jacksonville, at the mouth of the Hillsboro River, on Tampa Bay, and on the Atlantic Coast, the Seaboard Air Line, the Tampa and Gulf Coast, and the Tampa Northern railroads (Map: Florida, D 4). There is also steamship connection with the principal Atlantic and Gulf ports and Cuba, the West Indies, and Central America. Tampa has become a famous winter resort. Noteworthy are the Tampa Bay Hotel, De Soto Park, the scene of the encampment of the United States Volunteers during the Spanish-American War; the old government reservation; the Carnegie Library, Sulphur Springs, Ballast Point Park, the county courthouse, Elk's Home, the Church of St. Louis, and the Federal building. Tampa is an important shipping point through Port Tampa for phosphate, fruits, vegetables, turpentine, rosin, lumber, fish, and cattle. In the year ending June 30, 1913, the total trade of the customs district amounted to \$8,918,000, including exports to the value of \$4,326,000. The 1914 census showed manufactured products to the value of \$14,039,000, and an invested capital of \$9,858,000. The chief industry is the manufacture of Havana cigars, a large part of the world's supply being made here. There are foundries and machine shops, a fertilizer factory, and manufactories of wagons, automobile tops, jewelry, furniture, lamps, mattresses, safes and locks, brick and tile, etc. Fishing also is largely carried on. Pop., 1890, 5532; 1900, 15,839; 1910, 37,782; 1915, 51,521; 1920, 51,252.

**TAMPA BAY.** An inlet of the Gulf of Mexico on the west coast of Florida (Map: Florida, D 4). The bay proper is about 20 miles long, and has an average width of about 7 miles, the northern part being divided into Old Tampa Bay (about 12 miles long and 6 miles wide) and Hillsboro Bay (7½ miles long and about 4 miles wide). Its entrance is protected by a line of keys, or low islands, and it forms an excellent harbor with a depth of 22 feet in the main entrance, though the dredged channel to Port Tampa is 24 feet deep.

**TAMPAN.** A tick (q.v.) of southern Africa, remarkable for its very poisonous bite, found in Angola and southward, and described by Livingstone in his *Travels*. It attacks by preference the parts between the fingers or toes, attains the size of a pea, and when filled with blood is dark blue, and so tough that it cannot be burst by squeezing with the fingers. The first effect of the bite is mingled pain and itching, which ascends until it reaches the abdomen, and causes either violent vomiting and

purging, or fever. The tingling sensation lasts for a week.

**TAMPICO**, tām-pē'kō. A seaport in the state of Tamaulipas, Mexico, 206 miles northeast of the City of Mexico, on the Pánuco, near its mouth (Map; Mexico, K 6). The town is surrounded by lagoons, which make it very unhealthful. It has broad streets and squares, the largest of the latter, the Plaza Constitución, having a public garden in its centre. The most notable building is the parish church of the Jesuits. The town is connected by rail with the interior states of northern Mexico, of which it is the chief outlet. The city has experienced rapid development due to the exploitation of oil fields. In 1913 exports amounted to \$81,030,261, and included ixtle, rubber, guayule, chicle, and asphalt. Imports, chiefly manufactured articles from the United States, were valued at \$45,832,515. Pop. (est.), 35,000. Tampico was an Aztec city. In 1683 it was destroyed by the pirate Lorencillo and was not rebuilt till 1823. It received the name Santa Ana de Tamaulipas in 1834, and was the scene of a Mexican victory over the Spanish in 1827. In 1914 it was the scene of the Tampico incident (see MEXICO, *History*), and later was captured by the Constitutionalists.

**TAMSUI**, tām'sōŭ'ĕ (Chin., Freshwater). A port on the north coast of Formosa, opened to foreign residence and trade by the Treaty of Tientsin (1858), and continued as such by the Japanese. It stands at the mouth of the Tamsui River, 13 miles from Jai-peh, or Daihoker (Map: Japan, D 8). The principal exports are tea, rice, sugar, camphor, coal, flax, hemp, jute, etc., chiefly to China, Hongkong, British India, and the United States, and the imports are salt, flour, kerosene oil, cotton and woolen goods, lead, and other metals, tobacco, joss sticks, etc. The population is estimated at over 6000.

**TAM-TAM** (Hind., drum, onomatopoeitic in origin). An Indian or Chinese musical instrument. It consists of a metal disk concave in the middle and is suspended by a loop. The tone is produced by striking the disk with a stick having a soft knob made of felt or leather.

**TAM'WORTH**. A municipal borough and market town, on the borders of Staffordshire and Warwickshire, England, at the confluence of the Tame and Anker, 13 miles northeast of Birmingham (Map: England, E 4). Its chief buildings are the castle built on the site of a Saxon fort and the church of St. Editha, founded in the eighth century. It acquired in 1897 the historic castle which had descended through the female line of the Marmions to the Marquis Townshend. Market gardening, brickmaking, dyeing, wool stapling, and manufactures of tapes and small wares are carried on. From the beginning of the eighth century Tamworth was the chief Mercian royal residence. Burned by the Danes in 911, it was rebuilt by Ethelfleda, daughter of Alfred the Great. Pop., 1901, 7271; 1911, 7738. Consult Palmer, *History of Tamworth* (London, 1871-75).

**TANA**, tā'ná. A river in British East Africa (Map: Congo, G 3). It rises in numerous head streams in the southwest slope of Mount Kenia, and flows southeast after making a long detour to the north, emptying into the Indian Ocean. Its length is over 500 miles. Its upper course down to Balarti (Hameye) is that of a mountain stream, full of falls and cataracts. Its importance as a waterway into the interior of

Africa is considerably diminished by the bar which obstructs its entrance.

**TANA**. See TZANA.

**TAN'AGER** (from Neo-Lat. *Tanagra*, from Brazilian *tangara*, the native name of the bird). The popular name for the Tanagridæ, a family of birds having a conical beak, triangular at the base, the upper mandible notched towards the tip, and its ridge arched. The family is closely related to the finches, and about 350 species are known, all American and nearly all tropical. Only five species occur as far north as the United States and only two of these reach Canada. They are all birds of moderate or small size, 6 to 8 inches long, or less, of surpassingly gaudy plumage, though the brilliancy is mostly confined to the males. They are arboreal, feeding on fruit and insects, and have little power of song, but a few species sing well. The best known of the three North American forms is the scarlet tanager (*Piranga erythromelas*), the most brilliant bird of the northern United States—the male bright scarlet with black wings and tail; the female light olive-green above, greenish yellow beneath. The immature males are like the females, but have the black wings and tail, and the adult male assumes this plumage in winter. The scarlet tanager breeds as far north as New Brunswick and as far west as Kansas, but winters in Central and South America. It builds its nest near the end of a horizontal limb; the nest is a loose, shallow structure of twigs, weeds, and rootlets. The eggs are pale bluish with numerous reddish-brown spots. The scarlet tanager has a pleasing song. From New Jersey southward there is found from April to September the summer tanager (*Piranga rubra*), rose-red, brighter below, the wings fuscous margined with rose. The female is orange olive-green above, buffy yellowish green below. In habits, nesting, and song it resembles the scarlet tanager. From the eastern foothills of the Rockies to the Pacific there is found in summer the Louisiana or Western tanager (*Piranga ludoviciana*). The male is bright yellow, with the whole head crimson or scarlet, and the back, wings, and tail black. The female is exactly like the female scarlet tanager, except for white or yellowish markings on the wings. In nesting and other habits this bird resembles the others. Consult Robert Ridgway, *Birds of North and Middle America*, part ii (Washington, 1902), and general ornithologies. See Colored Plate with THRUSH.

**TAN'AGRA** (Lat., from Gk. *Távαρα*, modern Grimadha). An ancient city in eastern Bœotia close to the Athenian border. It did not play any part in ancient history, but near it was fought an important battle between the Athenians and the Spartans in 457 B.C. Through the treacherous desertion of the Thessalian cavalry the Athenians were defeated, but later in the same year at Ctenophyta in the same district they won a great victory which made them masters of Bœotia. During the Hellenistic and Roman periods Tanagra was a flourishing agricultural community, said to produce the best wine in Bœotia. It is now deserted, though the line of ancient walls is marked by mounds of rubbish, and there are remains of the theatre and other ancient buildings. The chief fame of the town is due to its extensive necropolis, first opened in 1874, and since then the scene of countless open and clandestine excavations. The tombs or graves have yielded the long series of

graceful and charming terra-cotta statuettes, known as Tanagra figurines. In many cases these were broken before being cast into the grave, and their significance has caused much discussion, in which an occult symbolism has not been proved. The high value attached to these little figures has led to much modern forgery, and it is often hard even for an expert to detect the imitations. Consult Fowler, Wheeler, and Stevens, *A Handbook of Greek Archaeology* (New York, 1909), and K. Baedeker, *Greece* (4th Eng. ed., Leipzig, 1909).

**TANAIS.** The ancient name of the Don.

**TANANÁ,** tá-ná'ná (South American name). One of the singing grasshoppers of the genus *Locusta*, common in Brazil, whose music is much admired by the natives, who keep it in little cages much as the Japanese keep crickets.

**TANANA (tá'ná-ná') RIVER.** The longest and most important of the affluents of the Yukon River, Alaska (Map: Alaska, K 3). It is navigated from the middle of May to the middle of October as far as Fairbanks (q.v.), 200 miles. Of its tributaries the Chena, Tolovana, and Volkmar are practicable for very small steamers, while the Kantishna has been navigated 200 miles.

**TANANARIVO,** tá-ná'ná-ré'vô. The capital of Madagascar. See **ANTANANARIVO**.

**TANANA VALLEY.** This region, watered by the Tanana and its tributaries, is the most important portion of the Yukon watershed. Area, about 25,000 square miles. Pop. (white), about 6,000, with some 30,000 acres under homestead. The native population, Tananas, decrease slowly in numbers. From 1903 to 1915 gold to the estimated value of \$66,000,000 was mined, the products of the Fairbanks district alone exceeding \$63,000,000. Coal beds, though low grade in quality, extend from the Delta River westward to the upper Nenana. In the Bonnefield district an area of 600 square miles of lignite coal outcrops, under favorable conditions for mining. Good grass, fertile soil, abundant timber (mostly spruce and birch) make portions of the Tanana valley the most desirable part of interior Alaska for permanent settlement.

**TAN'AQUIL.** The wife of Tarquinius Priscus.

**TANAUAN,** tá-ná'wán. A town of Leyte, Philippines, situated 10 miles from Tacloban. Pop., 1903, 18,256.

**TANAUAN.** A town of Luzon, Philippines, in the Province of Batangas. It is situated on the principal highway from Batangas to Manila, about 27 miles north of Batangas. The town was founded in 1584, on the shore of Lake Taal, but was destroyed in 1754 by an eruption of the volcano Taal (q.v.), and later rebuilt in its present position not far from the lake. Pop., 1903, 18,263.

**TANCRED** (c.1050-1112). Prince of Antioch, a hero of the First Crusade. The first authentic information respecting him is that he joined his cousin Bohemund in the First Crusade in 1096. They landed in Epirus, and took the oath of allegiance to the Greek Emperor, Alexius (q.v.). Tancred's exploits on the way to Syria; his quarrel with Baldwin for the possession of Tarsus; his valor before Antioch, where he took an oath that as long as he had 40 knights he would never withdraw from the expedition to Jerusalem; and the praises of his biographer, Radulph of Caen, have given him a fictitious im-

portance. After the conquest of Jerusalem he became Prince of Galilee. A quarrel with Baldwin, after Godfrey's death, caused him to give up his possessions in the Kingdom of Jerusalem. While Bohemund was in captivity he ruled over Antioch. When Bohemund died in 1111, Tancred became Prince of Antioch, where he died in 1112. Tancred has been made famous by Tasso in his *Gerusalemme Liberata*. For the actual facts during the most important period of his life, consult Bernhard Kugler, *Boemund und Tankred* (Tübingen, 1862), and Reinhold Röhricht, *Geschichte des Königreichs Jerusalem* (Innsbruck, 1898).

**TANCRED AND GISMUNDA.** A tragedy played before Queen Elizabeth in 1586, published by Robert Wilmot in 1591. It was founded on a story by Boccaccio, the substance of which makes the plot of Tale 39 in *Painter's Palace of Pleasure* (London, 1566-67).

**TANCRED DE HAUTEVILLE,** ôt'vêl'. A Norman noble, father of several sons who established by force of arms the Norman power in southern Italy and Sicily. The most celebrated of the brothers were Robert Guiscard and Roger I (q.v.).

**TANDY, JAMES NAPPER** (1740-1803). An Irish agitator, born in Dublin. During the American Revolution he took an active part in the effort to prevent the use of English goods in Ireland; was an enthusiast in the "volunteer movement"; on May 27, 1782, commanded the corps of artillery that guarded the approaches to the Irish Parliament when that body met to receive the answer of the ministry to the demand for legislative independence; and was one of the foremost in the volunteer convention of November, 1783. Ten years afterward when he was about to be tried for writing a seditious pamphlet called "Common Sense," he fled to the United States. In 1798 he went to Paris and was put in command of a vessel for an invasion of Ireland. He remained on Irish soil, however, but eight hours, and then went to Bergen, Norway, and from there by land to Hamburg. At the latter place he was seized and was delivered to the English, and upon his arrival in Ireland was condemned to death. Bonaparte, however, brought such pressure to bear in his favor that he was released. He soon after went to France and was made a general of division. He was the hero of the famous ballad, "The Wearing of the Green." Consult W. E. H. Lecky, *History of England in the Eighteenth Century* (new ed., 7 vols., New York, 1892-93).

**TANCIEV,** tá'ná-yéf, SERGEI IVANOVITCH (1856-1915). A Russian composer. He was born in the Province of Vladimir and studied at the Moscow Conservatory under Nicholas Rubinstein, Hubert, and Tchaikovsky. After his graduation in 1875, when he received the gold medal in two departments, he toured in Russia with Leopold Auer (q.v.) and won high praise as a pianist. At the Moscow Conservatory he became professor of harmony (1878), professor of piano (1881), and was director (1885-89). After that, until his death, which occurred at Dindkovo, he taught higher composition with signal success. His career as a composer began in 1881 with a sacred cantata (in commemoration of Nicholas Rubinstein) entitled *St. John of Damascus*. The list of his compositions includes, besides four symphonies, the opera *Orestes* (1895), numerous songs of high lyric quality, and much

chamber music that alone would have made the composer famous. His last great work, *On Reading a Psalm*, a cantata in the style of Bach, was successfully performed in 1915. He wrote also an elaborate treatise on *Imitative Counterpoint in Strict Style*; and among his papers was found an almost completed treatise on *Canon and Fugue*. As a composer Taneiev was neither a Nationalist nor an ultra-Modernist, but a true Classicist. Both as teacher and as composer he exercised a wide influence in Russia.

**TANEY**, tā'ni, ROGER BROOKE (1777-1864). An eminent American jurist, Chief Justice of the United States Supreme Court. He was born in Calvert Co., Md., graduated at Dickinson College, Pa., studied law at Annapolis, and in 1799 was admitted to the bar. In 1823 he removed to Baltimore, where he succeeded William Pinkney and Luther Martin as head of the Maryland bar. In 1827 he was elected Attorney-General of the State, and, having become a Democrat and a supporter of Andrew Jackson, was appointed Attorney-General of the United States in 1831. In this capacity he became one of Jackson's most trusted counselors, encouraged him to remove the United States Bank deposits, and upon the refusal of William J. Duane, then Secretary of the Treasury, to obey Jackson's orders to this effect, was appointed in Duane's stead, though his appointment was never confirmed by the Senate. Taney promptly removed the deposits and thus further won the confidence of his chief. In 1836 he succeeded John Marshall as Chief Justice of the United States Supreme Court. In this capacity he sustained in the main the high reputation of his distinguished predecessor for legal learning and acumen, though as a result of the passions engendered by the approaching civil strife some of his opinions were severely criticized. He wrote the opinion of the court in many important cases, the most notable being that of *Dred Scott*. (See *DRED SCOTT CASE*.) During the Civil War Chief Justice Taney gave opinion in the noted case of *Ex parte Merryman* in answer to an application for a writ of habeas corpus in behalf of a citizen of Baltimore who had been arrested by a United States officer on a charge of treason, denying in strong and vigorous language the right of the President to suspend the writ of habeas corpus and affirming that that power was vested in Congress alone. A memoir of Taney's life, in part an autobiography, was published in 1872 by Samuel Tyler.

**T'ANG**, tāng. One of the seven most celebrated dynasties of China. It lasted from 618 to 907 and was founded by Li Yuan, a soldier and a descendant of one of the princely houses, who, after a reign of eight years, during which many reforms were introduced, abdicated in favor of his second son, Li Shih-min, the real unifier of the Empire and the most illustrious of the T'ang rulers (627-649). With the twelfth Emperor decay began to set in and in 907 the line came to an end. In 923 a descendant of one of the T'ang emperors established the Posterior T'ang, which came to an end in 936 under its fourth Emperor.

The T'ang is undoubtedly one of the most brilliant periods of Chinese history. The Empire was extended to the Caspian Sea and China itself was divided into 15 provinces. In 628 a maternal uncle of Mohammed visited China and built the mosque at Canton, and a century and a half later 4000 Mohammedan soldiers,

whose descendants now form an important element of the population, settled in the country. Learning and literature were fostered, the Han-lin Yuan (q.v.) had its beginning, and Buddhism, Taoism, and even Nestorian Christianity flourished under Imperial patronage. Paper money was then first used and the Peking *Gazette* was founded.

**TANGANYIKA**, tān'gān-yē'kā. A large lake in Central Africa, extending from lat. 3° 16' to 8° 48' S., and from long. 29° 20' to 31° 20' E. (Map: Africa, H 5). It lies in the western branch of the Great Rift valley (q.v.), which is interrupted at the south end of the lake by a plateau, but continued farther to the southeast as the basin of Lake Nyassa. Tanganyika extends in a north-northwest and south-southeast direction, with a length of 400 miles and a breadth of 20 to 40 miles. Its area is estimated at over 12,000 square miles. Its drainage basin, which includes a narrow strip of fertile lowland along either shore, has the appearance of a vast chasm with precipitous rocky cliffs, reaching a height of 4200 feet above the level of the lake, which is 2700 feet above the sea. The depth is very great, ranging in the greater portion from 500 to over 2000 feet, and the lake has but a few shoals, reefs, or islands. There are, however, floating islands of vegetation, the shores being often very densely forested with palms. Navigation is also rendered dangerous by severe hurricanes and tornadoes to which the basin is subject. The lake is fed largely by the seasonal rain (October to March), and discharges into the Congo through the Lukuga, which leaves it near the middle of the western shore. This discharge, however, is intermittent, and the level of the lake is subject to periodic fluctuations, each of which may range over a series of years. The fall of the lake level in recent times has amounted to two feet annually. Though the water is, as a whole, fresh, it has in some portions a tendency to become brackish. Besides the usual fresh-water fish, crocodiles, and hippopotami, there are a number of peculiar isolated groups of deep-water mollusks and crabs which are asserted to be of marine origin, and which point to a connection with the sea, probably in Jurassic times.

The largest town is Ujiji, on the east shore. Lake Tanganyika was discovered in 1858 by Burton and Speke, and later explored by Livingstone, Cameron, Stanley, and others. Consult Peters, *Das deutsch-ostafrikanische Schutzgebiet* (Munich, 1895).

**TANGELO**, tān'jē-lō. A name given to the fruits obtained from hybrids between the tangerine and pomelo. The tangelo has the loose skin of the tangerine and the sprightly acid flavor of the pomelo, with less bitterness. It is used principally as a breakfast fruit. Consult United States Department of Agriculture *Yearbook*, 1904 (Washington, 1905).

**TANGENT** (Lat. *tangens*, pres. p. of *tangere*, to touch). In elementary work, an unlimited straight line which meets a curve in but one point without cutting it. This definition is, however, not general. If we have a point *P* on a curve, with chords drawn from *P* to one of the arcs terminated by *P*, then if a line can be drawn from *P* so that chords of unlimitedly short length make angles of unlimited smallness with this line, the line is called a tangent to the curve at *P*. This more general definition of tangent is illustrated in the figures (page 824).

In Fig. 1 we have the elementary idea of tangent. In Fig. 2 we see that a tangent at  $P$  may cut the curve at some other point. In Fig. 3 we see that a tangent at  $P$  may even cut the curve at that point. The point  $P$  in any of

FIG. 1.

FIG. 2.

FIG. 3.

these cases is called the point of contact or point of tangency. A tangent may be thought of as the limiting position of a secant, the point of tangency being the point in which the points of intersection of the secant with the curve coincide. In the circle there is but one distinct tangent at any point in the circumference, and this is perpendicular to the radius at that point. The segments of two tangents to a circle from an external point, limited by the point and the points of contact, are equal. If the point moves up to the circumference the segments become zero and the tangents coincide; if the point moves inside the circumference the tangents become imaginary. (See CONTINUITY.) All conic sections being of the second class (see CURVE) admit of but two tangents from any point. Curves belonging to higher classes admit of a greater number, depending upon the class. Tangents are of different orders of contact (see CONTACT) according to the number of coincident points at the point of tangency, and thus serve to distinguish various singularities of curves. (See CURVE.) In coördinate geometry the projection, upon the  $X$  axis, of the segment of the tangent between the point of contact and the  $X$  axis is called the subtangent. An important class of tangents are known as asymptotes (q.v.). In the geometry of surfaces the tangent plane corresponds to the tangent line of curves. The extensive list of properties involving tangents is best obtained from works on analytic geometry.

**TANGERMANN**, täng'ér-män, WILHELM (1815-97). A German Old-Catholic theologian, known as an author by the pseudonym Victor Granella. He was born at Essen-on-the-Ruhr and studied theology at Münster and Munich. Ordained a Roman Catholic priest in 1845, he was appointed chaplain at Neuss in 1846 and at Unkel in 1862. In 1870 he was deprived of his office because of refusal to acknowledge the Vatican's decrees, and afterward he was identified with the Old-Catholic movement. From 1872 to 1888 he was in charge of the congregation at Cologne. His writings include: *Wahrheit, Schönheit, und Liebe, Philosophisch-ästhetische Studien* (1867); *Philosophie und Christentum in ihren Beziehungen zur Kultur und Religionsfrage* (1876); *Das liberale Princip* (1883; 2d ed., 1886); *Natur und Geist* (1894); *Erkenntnis und Liebe, die schönsten Leitsterne des Lebens* (1906).

**TANGERMÜNDE**, täng'ér-mün'de. A town in the District of Magdeburg, Prussia, 63 miles west of Berlin, on the Elbe (Map: Germany, D 2). The town still retains its old walls, gates, and towers, its twelfth-century Church of St. Stephen, an ancient castle, now the district building, and the old council house. There are a large sugar refinery, mills for manufacturing rapeseed oil and bone meal, and boat-

building establishments. Pop., 1900, 11,524; 1910, 14,001.

**TANGHIN**, täng'gin (Malagasy name), *Cerbera tanghin*. A tree of the family Apocynaceae. The kernel of its fruit was formerly used in Madagascar, where the tree is native, to determine the guilt or innocence of persons charged with witchcraft and like odious crimes.

**TANGIER**, täng-jér'. The chief seaport of Morocco, on the Bay of Tangier, in the Strait of Gibraltar, eight miles east of Cape Spartel and 35 miles southwest of Gibraltar (Map: Africa, D 1). The climate is healthful and temperate and through European influence the sanitary conditions of the town have been greatly improved. Inland is the Spanish protectorate of Morocco, in which Tangier is not included, but, by the Franco-Spanish treaty of Nov. 27, 1912, constitutes, with a territory of some 600 square kilometers, a special international district. Tangier is surrounded by ancient ruins of walls and by garden areas. It is picturesquely Oriental and its life is highly interesting. The white Moorish houses, amid towers and gates, rise above one another from the sea in the form of an amphitheatre, the highest point being crowned by a castle. The houses are of one story, the streets steep and too narrow for wagons or carriages. The main street leads from the harbor on the east to the new market and to the Socco de Barra on the southwest. It passes the Great Mosque, whose handsome gate and tower are noteworthy. Near by is the Small Socco with its interesting bazaars, the business centre of the town. For the accommodation of the numerous visitors and tourists there are a number of European shops and modern hotels. The Kasba, or castle, dating from the fifteenth century, stands on the plateau in the northern part of the city. The plateau extends from the lofty Marshan towards the sea and furnishes a superb view. The castle or citadel is a dilapidated mass of buildings. The adjacent palace of the Sultan and the residence of the Governor are imposing edifices. There are a Catholic chapel, several synagogues, and a hospital. Tangier is lighted by electricity. The harbor is the best in Morocco, although it is both small and shallow. Imports and exports in 1912-13, \$848,952 and £200,171; in 1913-14, \$978,173 and £136,331. Trade is largely in the hands of the Jews. Pop., from 40,000 to 50,000, including 6000 Christians and 7000 Jews.

Tangier is the Roman Tingis and was the capital of Mauretania Tingitana. It was held in turn by the Vandals, Byzantines, Arabs, and Portuguese, who obtained possession of it in 1471. After being held by the Spaniards and again by the Portuguese it came to the English in 1662 as part of the dowry of Catharine of Braganza, wife of Charles II, but was abandoned by them to the Moors in 1684. As a result of the Algeciras conference of 1906, a joint Franco-Spanish police force was organized. Details for the administration of Tangier as an international district were not completed in 1914.

**TANGLE**. A kind of seaweed. See CARRAGEEN; LAMINARIA.

**TANGLEWOOD TALES**, THE. A volume of stories for children by Nathaniel Hawthorne (1853).

**TANGO**, täng'gô; Sp. täng'gô. See DANCING.

**TANGUAY**, täng'gá, CYPRIEN (1819-1902).

A Canadian clergyman and genealogist. He was born in the city of Quebec, graduated at the Quebec Seminary in 1839, and was ordained a Catholic priest in 1843. He removed in 1860 to St. Germain, and founded Rimouski College and the convent of Notre Dame. In 1865 he entered the service of the Canadian government, and in 1867 was sent to Paris to examine the French archives in connection with Canadian history. He was one of the original fellows of the Royal Society of Canada (1882). In 1887 he was sent abroad to report upon the historical archives of Europe. He published the important *Dictionnaire généalogique des familles canadiennes* (7 vols., 1871-90) and *Le répertoire du clergé canadien par ordre chronologique* (2d ed., 1893).

**TANIER.** See COCCO.

**TAN'IS.** The Carthaginian moon goddess, called by the Phenicians Astarte (q.v.).

**TANIS** (Lat., from Gk. *Távis*, Egyptian *Za'net*, Hebrew *Zo'an*). A city of ancient Egypt in the northeast corner of the Delta. It was situated on the right bank of the Tanitic branch of the Nile, near the site of the modern fishing village of San. Tanis was the capital of the fourteenth nome of Lower Egypt, and was a place of importance in very early times. The kings of the Sixth dynasty founded there a great temple which was subsequently restored and enlarged by their successors of the Twelfth and Thirteenth dynasties, and the city was for some time the capital of the Hyksos rulers. Under the Nineteenth dynasty it was strongly fortified as a base of military operations against Palestine and Syria, and Rameses II, who established his residence there, restored the ancient temples and greatly embellished the city. The Twenty-first dynasty, of Tanitic origin, made the city the capital of Egypt, and at the time of the Assyrian invasions in the seventh century B.C. it was the seat of a prince. Until the founding of Alexandria it was one of the chief commercial cities of Egypt, but the silting up of the Tanitic mouth of the Nile diverted its trade to the new capital of the Ptolemies, and it gradually fell into ruins. Excavations of the site, conducted by Mariette in 1860 and by Petrie in 1883-84, brought to light the remains of extensive temple buildings, many statues and sphinxes, and no less than 14 obelisks. Tanis is undoubtedly the biblical Zoan which in Numbers xiii. 22 is said to have been built seven years later than Hebron, and it is identified by many Egyptologists with the city of Raameses, which the Israelites were obliged to fortify (Ex. i. 11). Consult: W. M. Flinders Petrie, *Tanis* (London, 1885-88); E. A. T. Wallis Budge, *A History of Egypt* (New York, 1902); J. H. Breasted, *Ancient Records of Egypt* (Chicago, 1907).

**TAN'ISTRY** (from *tanist*, from Ir., Gael. *tánaiste*, OIr. *tanaise*, *tanaiste*, next heir to an estate). An ancient Celtic law of succession by which property or political power descended not to the children, but to the eldest and worthiest of the surviving kinsmen of the deceased lord. The rights thus transferred were felt to be vested rather in the tribe than in the individual.

**TANJAY**, tăn-hŷ'. A town on the east coast of Negros, Philippines, in the Province of Negros Oriental, situated 19 miles from Dumaguete, 1½ miles inland on a river of the same name. Pop., 1903, 11,894.

**TANJORE**, tăn-jōr'. The capital of a district of Tanjore, in the Province of Madras, Brit-

ish India, 48 miles west of Negapatam, in the valley of the Kaveri River, one of the richest agricultural sections in India (Map: India, D 7). The large temple, dating from the eleventh century, is one of the finest examples of the pagoda style of architecture in existence. There are several concentric rectangles, the outer measuring 415 by 800 feet. The leading architectural features are the great gopura, a pyramidal tower 200 feet high, and the handsome embellished shrine of Kartikeya. Another striking edifice is the palace of the Raja, constructed in 1550. It has many sculptures and pictures, together with a library containing valuable Sanskrit manuscripts. Schwarz's Church, the English Church, St. Peter's College, the Prince of Wales Medical School, and People's Park are also of interest. Tanjore has manufactures of jewelry, carpets, copper utensils, and objects in repoussé work. Pop., 1901, 57,870; 1911, 60,341. Tanjore was the capital of a Hindu principality until the overthrow of the Chola dynasty by the Mahrattas in 1678. During its early history it was one of the most important cities in southern India. The English obtained control in 1799.

**TANKAGE.** A name applied to a product, used mainly for fertilizing purposes, which is prepared from the residue resulting from the treatment of abattoir and slaughterhouse refuse with steam and hot water in closed tanks for the removal of fat; a process commonly known as tanking. Tankage is variable in composition, depending upon the materials used in its preparation and the process of manufacture, but is generally rich in nitrogen, and it is this element which mainly determines its value as a fertilizer. According to Voorhees, two distinct kinds of tankage are ordinarily prepared: (1) concentrated tankage, containing from 10 to 12 per cent of nitrogen with very small percentages of phosphoric acid; and (2) crushed tankage, of which there are several grades, containing from 4 to 9 per cent of nitrogen and 3 to 12 per cent of phosphoric acid. Products containing more than 12 per cent of phosphoric acid are known as bone tankage, and are properly classed with bone fertilizers (q.v.). The term tankage is also sometimes applied to the product obtained by drying, and in some cases partially charring, city garbage. This garbage tankage is more variable in composition and less valuable as a fertilizer than true tankage, although, like the latter, its value as a fertilizer depends mainly upon the amount and availability of its nitrogen. The nitrogen of meat and bone tankage of good quality has been found to be about 60 per cent as effective as plant food as that of nitrate of soda, which is taken as the standard. Tankage is therefore one of the most valuable sources of organic nitrogen for fertilizing purposes. Tankage is also used with good results as a concentrated feeding stuff, especially for feeding hogs. When used in combination with corn it supplies the deficiencies, from a feeding standpoint, of that grain in protein and ash constituents and thus furnishes a better-balanced ration.

**TAN'NAHILL**, ROBERT (1774-1810). A Scottish poet. He was the son of a silk weaver of Paisley. He was apprenticed to his father and passed most of his life in Paisley at the loom. As a song writer he possessed a spontaneity akin to that of Burns. Among his best songs are "Bonnie Wood o' Craigielee," "Sleepin' Maggie," "Braes o' Gleniffer," "Gloomy Winter's noo awa'," and "Jessie the Flower o' Dunblane."

Suffering from melancholia, Tannahill drowned himself in a canal near Paisley. In 1874 the centenary of his birth was observed; and in 1883 a bronze statue was erected to his memory in the Paisley Abbey burying ground. Consult the complete edition of *Poems*, ed. by Semple (Glasgow, 1873), which includes a full biography; selections in Miles's *Poets and Poetry of the Century* (London, 1891 et seq.).

**TANNEGUY, CHARLES MARIE.** See DUCHATEL, COUNT.

**TANNENBERG.** A village in the District of Allenstein, Prussia, with a population of about 500. On July 15, 1410, the Poles and Lithuanians inflicted a crushing defeat on the Teutonic Knights here. In August, 1914, Tannenberg was the scene of a great German victory over the Russians. The battle lasted seven days and was fought over several villages, the most important of which were Mühlen, Gilgenheim, Hohenstein, Allenstein, Soldau, Nerdenburg, Wilenburg, and Ortelsberg. The Germans held the centre of their line near Tannenberg and turned both flanks of the Russian army. Though outnumbered by the Russians 230,000 to 135,000 they inflicted such a severe defeat that it broke the Russian offensive against Königsberg. It is estimated that the Russians lost 70,000 killed and wounded, besides 95,000 prisoners. See WAR IN EUROPE.

**TANNER, HENRY OSSAWA** (1859- ). An American historical painter, the son of a bishop of the African Methodist Episcopal church. He was born at Pittsburgh, Pa., and studied at the Pennsylvania Academy of Fine Arts under Thomas Eakins, and under Jean Paul Laurens and Benjamin Constant in Paris, where he thenceforth resided. His paintings are landscapes and especially biblical subjects, which he renders in a naturalistic manner, yet with deep religious sentiment. Good examples include the "Raising of Lazarus" (Luxembourg, Paris); "Christ at the Home of Mary and Martha" (Carnegie Institute, Pittsburgh); "Christ and Nicodemus" (Pennsylvania Academy, Philadelphia); "The Two Disciples at the Tomb" (Art Institute, Chicago), and the "Annunciation" (Wilstach collection, Philadelphia). He was elected an associate of the National Academy in 1909, and received the Lippincott prize, Pennsylvania Academy (1900), and medals at Paris (1900), Buffalo (1901), St. Louis (1904), and San Francisco (1915).

**TANNER, HENRY S.** (1786-1858). An American geographer, born in New York City. He studied engraving and settled in Philadelphia, where, with his brother, he established a business in publishing maps, atlases, and geographical works. In 1850 he removed to New York City, where he died. His publications included many maps of different sections of North America.

**TANNER, THOMAS** (1674-1735). An English antiquary, born at Market Lavington, in Wiltshire, where his father was vicar, and educated at Queen's College, Oxford. He was ordained deacon in 1694 and was appointed chaplain of All Souls' College in 1695. He became canon of Ely (1713), canon of Christ Church, Oxford (1724), and Bishop of St. Asaph (1732). He is known chiefly for *Notitia Monastica, or a Short History of the Religious Houses in England and Wales* (1695) and the *Bibliotheca Britannico-Hibernica*, a valuable account of the authors that flourished in the three kingdoms

up to the seventeenth century (posthumous, 1748). With him Antony à Wood (q.v.) left additional "lives," which appeared in the second edition of *Athenæ Oxonienses* (1721). Tanner bequeathed a large body of manuscripts to the Bodleian Library at Oxford.

**TANNERY, tà'ne-ré', PAUL** (1843-1904). A French scholar, born at Nantes. He was educated in the Paris Polytechnic School. For two years he gave a course in the Sorbonne on the history of arithmetic, and for five years filled Professor Lévêque's chair in the history of Greek and Latin philosophy in the Collège de France. Aside from articles in periodicals he published: *Pour l'histoire de la science hellène* (1887); *La géométrie grecque* (1887); *La correspondance de Descartes dans les inédits des fonds Libri* (1893); and *Recherches sur l'histoire de l'astronomie ancienne*. Consult *Biographisches Jahrbuch* for 1906 (Berlin).

**TANNHÄUSER, tän'hoi-zër.** A German knight and minnesinger of the thirteenth century, probably a Bavarian by birth, who enjoyed the favor of Duke Frederick II of Austria. Little is known historically of his career, and he disappears entirely after the death of Conradin (1268). His lyrics are in the main mocking and sensuous. One of the latest of them, a penitential song, may have led to his identification with the hero of the old Teutonic legend of the Venusberg or Hill of Venus. This was a region within a mountain near the Wartburg, in the Thuringian Forest, where Venus reigned, and whence no one save Tannhäuser ever escaped. Here Tannhäuser, in the legend, lived with her until conscience smote him. He escaped, with the aid of the Blessed Virgin, and set out on a pilgrimage to Rome, to obtain pardon for his grievous sin. According to the story, Pope Urban IV refused to pardon the sin until the staff in the Pope's hand should sprout. Tannhäuser returned to the Venusberg, but the wand meantime put forth green leaves by a miracle, to show the extent of the divine mercy. Modern versions of the legend were made by Tieck, Heine, Geibel, and others; and in Swinburne's *Laus Veneris* Tannhäuser is conceived as having returned irredeemably to the Venusberg. But better known than any is the famous dramatic treatment by Richard Wagner in his opera *Tannhäuser* (1845), whose libretto follows E. T. A. Hoffmann in identifying Tannhäuser with Heinrich von Ofterdingen and introducing him into the contest of the minstrels on the Wartburg. The works of the historic Tannhäuser were first edited by Von der Hagen on his *Minnesinger* (1848). For these consult: Oehlke (Königsberg, 1890) and Siebert (Berlin, 1894); for the legend: Sabine Baring-Gould, *Curious Myths of the Middle Ages* (London, 1884), Grisse, *Der Tannhauser und der ewige Jude* (2d ed., Dresden, 1890), and E. Elster, *Tannhäuser in Geschichte, Sage, und Dichtung* (Bromberg, 1908); and for the opera, *Tannhäuser, Translated into Poetic Narrative Form*, by Oliver Huckel (New York, 1906).

**TANNHÄUSER.** An opera by Richard Wagner (q.v.), first produced at Dresden, Oct. 21, 1845; in the United States, April 4, 1859 (New York).

**TANNIN** (from *tan*, OF., Fr. *tan*, oak bark for tanning, from Ger. *Tanne*, fir, oak), **TANNIC ACID**, **GALLOTANNIC ACID**, or **DIGALLIC ACID**,  $C_6H_2(OH)_3COOC_6H_2(OH)_2COOH$ . An odorless and almost colorless powder as found in com-

merce, soluble in water, alcohol, acetone, glycerin, and various oils, occurring in Turkish and Chinese gallnuts and in other plants. It has a bitter, astringent taste, and becomes yellow if exposed to the action of light. It is used as an astringent in medicine and as a mordant in dyeing, and also in the manufacture of ink and of gallic and pyrogallic acids. Solutions of tannin reduce silver carbonate to metallic silver; they also reduce Fehling's solution (q.v.) and certain other substances, and precipitate gelatin and albumin from their solutions. On the other hand, solutions of tannin may be precipitated by the addition of various salts and acids, including common salt, sal ammoniac, the acetate as well as the sulphate of potassium, hydrochloric and sulphuric acids, etc. According to one method, tannin is procured by extracting the powdered gallnuts, which contain it in large quantities, with a mixture of alcohol, ether, and water; the layer of water then contains practically all the tannin; it is separated, purified by shaking with an excess of ether, and evaporated at a gentle heat. The residue obtained may be purified by dissolving in a dilute solution of common salt, and reprecipitating from this by adding an excess of salt in the solid state. With ferric salts tannin produces the well-known precipitate which is the coloring substance of ordinary black ink. The names "tannin" and "tannic acid" are also applied to a variety of other substances of vegetable origin and having properties more or less similar to those of galltannic acid: they are all astringent, transform hide into leather, give blue or green coloration with salts of iron, etc. Some of the more important of these may be noticed here.

**Alder Tannin**,  $C_{27}H_{28}O_{11}$ . A reddish-brown substance soluble in dilute alcohol and quite soluble in hot water; its solutions give a green precipitate with ferric salts. It may be prepared by extracting sawdust from *Alnus glutinosa* with boiling water, precipitating the extract with lead acetate, and decomposing with sulphureted hydrogen; the precipitate, which now contains both the tannin and lead sulphide, is extracted with alcohol; thus the tannin is isolated.

**Caffetannic Acid**,  $C_{15}H_{18}O_6$ . This is found in coffee berries and in other vegetable products. It is soluble in water and in alcohol, and its solutions give green coloration with ferric salts. It may be prepared by extracting coffee berries with alcohol, diluting with water, filtering, boiling the filtrate, and precipitating it with lead acetate; the precipitate obtained is shaken with alcohol, in which it is caused to dissolve by decomposing with sulphureted hydrogen, and then the caffetannic acid is isolated by filtering and evaporating the solution to dryness.

**Fraxitannic Acid**,  $C_{28}H_{32}O_{14}$ . A substance found in the leaves of the ash tree. It may be obtained by extracting with water, precipitating the extract with lead acetate, and dissolving the precipitate in boiling aqueous acetic acid. The tannin is then isolated by a somewhat elaborate process, involving fractional precipitation with ammonia, treatment of the purest fractions with sulphureted hydrogen, etc. (Consult *Monatshefte für Chemie*, vol. iii, p. 745.) Pure fraxitannic acid is a golden-yellow powder, whose solutions give dark-green coloration and precipitate with ferric salts.

**Quercitannic Acid**. A substance, or perhaps several very similar substances, of uncertain composition, found in the leaves and bark, but

not the wood, of the oak. It is also probably contained in tea. Extracts containing quercitannic acid are largely used in tanning. From these extracts the acid may be isolated by diluting with water, allowing to settle, filtering, precipitating the filtrate with hydrochloric acid, washing and drying the precipitate, dissolving it in strong alcohol, and mixing the alcoholic solution with somewhat more than an equal volume of water; the precipitate thus produced is rejected; on filtering, the liquid is evaporated to dryness, the reddish-white residue being practically pure quercitannic acid—a substance soluble in dilute alcohol and sparingly in cold water. Quercitannic acid gives a green coloration with ferric salts.

**Quercinic Acid**. A light brownish-yellow substance found in oak wood, and distinguished from quercitannic acid in that its aqueous solution gives blue coloration with ferric salts.

**Quinotannic Acid**,  $C_{14}H_{16}O_6$ . A light-yellow substance found in cinchona bark. It is soluble in water, alcohol, and ether, and its solutions give a green precipitate with ferric salts. It may be prepared by extracting cinchona bark with water, adding burnt magnesia, filtering, precipitating the filtrate with lead acetate, decomposing the precipitate with aqueous sulphureted hydrogen, again filtering, precipitating this filtrate with basic lead acetate, dissolving the precipitate in dilute acetic acid, adding ammonia, treating this last precipitate with sulphureted hydrogen, and, finally, evaporating the resulting solution to dryness in vacuo.

**Artificial Tannin**. A number of substances similar in composition and properties to the natural tannins have been obtained synthetically by Löwe, Schiff, Böttiger, and others.

Consult Trimble, *The Tannins: A Monograph on their History, Preparation, etc., with an Index to the Literature of the Subject* (Philadelphia, 1892-94), and Sir T. E. Thorpe, *Dictionary of Applied Chemistry* (rev. ed., 5 vols., New York, 1912-13).

**TANNING**. See LEATHER.

**TANN-RATHSAMHAUSEN**, tăn-răt/sâm-hou'zen, LUDWIG SAMSON, BARON VON UND ZU DER (1815-81). A German general, born at Darmstadt. He entered a Bavarian regiment of artillery in 1833, was transferred to the general staff in 1840, and, becoming aid-de-camp to Crown Prince Maximilian in 1840, was soon afterward promoted to the rank of major. In 1849-50 he took a conspicuous part in the Schleswig-Holstein campaign, and after his return to Bavaria was again aid-de-camp to King Maximilian, was made major general in 1855 and commanding general at Augsburg in 1861 and subsequently at Munich. In 1866 he was chief of staff of Field Marshal Prince Charles, commander in chief of the South German contingents, and having been appointed general of infantry and commander of the First Army Corps in 1869, led it with distinction in the campaign of 1870, at Wörth, Beaumont, and Sedan. Given command over the combined forces operating on the Loire, he reduced Orléans, afterward fought victoriously under the Grand Duke of Mecklenburg in several bloody engagements, and rejoined the besieging forces before Paris. For his biography, consult Hugo von Helvig (Berlin, 1882) and Gebhardt Zernin (Darmstadt, 1883).

**TANOAN** (tăn'ô-an) **STOCK** (from *Tahano*, the native name of Tano pueblo). A family of languages spoken in a group of pueblo villages

upper Rio Grande valley, New Mexico. The most important modern villages are Jemez, Isleta, Picuris, Pojoaque, San Juan, Santa Fe, Sandia, and San Ildefonso. A number of villages occupied during the Spanish period are now in ruins. At that time they were known under the names Tewa and Tigua. In these villages are very much what they were when first visited by Spanish explorers many years ago. They are regarded as the most typical pueblo group and probably the oldest from which the others derived their culture. See INDIANS, AMERICAN; ISLETA; PUEBLO. Consult Bandelier, *Papers of the Archaeological Institute of America*, vol. i (Boston, 1881).

**TAN'REC.** See TENREC.

**TANSILLO**, tăn-sil'lo, LUIGI (1510-68). An Italian poet of the Petrarchistic group, born at Venosa, Province of Potenza. He early entered court service and in 1535 joined the bodyguard, formed of one hundred nobles, of Don Pedro de Toledo, the Spanish Viceroy of Naples, with whom and with whose son, Don García, he stood in great favor. He accompanied them on their expedition against the Turks and fought with conspicuous bravery. Subsequently he was capitano di giustizia at Gaeta and died at Teano. His ingenious and sensuous poem *Il vendemmiatore* (1534; trans. by Mercier as *Jardin d'amour*, 1798) established his literary reputation, but caused his writings to be placed on the Index by Paul IV. To atone for it, Tansillo resumed a religious epic *Le lagrime di San Pietro*, begun in 1539, but left it unfinished. His two didactic poems *La balia* (trans. by William Roscoe) and *Il podere* are among the best in Italian literature. His lyrics, inspired by impassioned love for a high-born lady, are replete with fervor and fine descriptions of nature. They were turned to philosophical meanings in the *Heroic Furies* of Giordano Bruno, whence some were translated by J. A. Symonds. In the *Stanze a Don Pedro di Toledo* (1547) he depicts with consummate art the luxurious gardens of the Viceroy by the sea. Consult: *Poesie liriche edite ed inedite* of Tansillo (ed. by Fiorentino, Naples, 1882); *Capitoli giocosi e satirici* (ed. by Volpicella, ib., 1870); Fiorentino, *Aneddoti tansilliani e danteschi* (ib., 1883); Flamini, *L'egloga e poemetti di L. T.* (ib., 1893).

**TANSY** (OF. *tanassie*, Fr. *tanaisie*, from ML. *athanasia*, tansy, from Gk. *athanasia*, *athanasia*, immortality), *Tanacetum*. A genus of plants of the family Compositae, natives of the temperate parts of the Old World. Common tansy (*Tanacetum vulgare*), a perennial, has long been cultivated in gardens and is naturalized in many parts of North America. The deep-green leaves and yellow flowers have a strong aromatic smell and a bitter taste. The leaves contain a volatile oil, and the younger ones have been used for flavoring puddings, cakes, omelets, etc., and were formerly used in medicine, but are now rarely used even in domestic practice. Some curious Easter customs linger in many parts of England connected with the use of tansy cakes and puddings which were originally intended to represent the use of bitter herbs at the paschal feast. See Chambers, *Book of Days* (new ed., 2 vols., Philadelphia, 1911).

**TANTA**, tăn'tā, or **TANTAH**. The capital of the Province of Gharbieh, Lower Egypt, situated in the Delta, about 60 miles north of Cairo (Map: Egypt, C 1). It has a palace of the Khedive and a fine mosque and is noted for its

fairs and festivals, which are visited by thousands of Moslem pilgrims and traders. Pop., 1907, 54,437.

**TAN'TALITE** (from Neo-Lat. *tantalum*, *tantalum*). An iron and manganese tantalate which merges chemically by insensible gradations into the iron and manganese niobate, columbite (q.v.). An intermediate product between these two is a niobate and tantalate of iron and manganese. The columbite-tantalite series crystallizes in the orthorhombic system. Tantalite has a submetallic and often brilliant lustre and is brown to iron black in color. It occurs in granitic and feldspathic veins in the form of crystalline granules and cleavable masses. The iron in this mineral is frequently replaced by manganese, giving rise to a variety known as *manganotantalite*.

**TANTALUM** (Neo-Lat., from Lat. *Tantalus*, father of Niobe; so called from its close resemblance to the metal niobium). A metallic element discovered by Ekeberg in 1802. It occurs associated with the element columbium in the minerals tantalite, yttriotantalite, columbite, and other heavy rare minerals. It is obtained chiefly from tantalite. Its separation from columbium, on account of the extremely close similarity of the two elements, is a long and complicated operation. Tantalum (symbol, Ta; atomic weight, 181.5) is a black powder that assumes an iron-gray metallic lustre under a burnisher, and when gently heated ignites in the air, forming the pentoxide, Ta<sub>2</sub>O<sub>5</sub>, which in turn combines with bases to form a series of salts called tantalates. Metallic tantalum melts at 2798° C. (5068° F.). Wrought tantalum is exceedingly hard and tough and has been used in the manufacture of pen nibs. The metal, further, resists all ordinary acids, even aqua regia, whence its great usefulness for chemical purposes. Finally, tantalum is finding an increasing use in the manufacture of steel.

TANSY.

**TANTALUM INCANDESCENT LAMPS.** See ELECTRIC LIGHTING.

**TAN'TALUS** (Lat., from Gk. *Tánταλος*). In

TANSY, ETC.

1. TANSY (*Tanacetum vulgare*).  
2. WILD CARROT (*Daucus Carota*).

3. ARROW-WOOD (*Viburnum acerifolium*).  
4. THISTLE (*Cnicus lanceolatus*).

Greek legend, King of the region about Mount Pelion in Lydia, son of Zeus and father by Pelops (q.v.), Broteas, and Niobe (q.v.). As favorite of Zeus he was admitted to the gatherings of the gods, but, having offended them grievously in some way, he was visited with extreme punishment, so that he became one of the typical figures in Tartarus. There Tantalus was plunged into a deep pool, whose waters receded whenever he stooped to drink, while over his head hung clusters of fruit which were ever kept just beyond his reach. Another version represented him as cowering beneath a huge rock which constantly threatened to fall and crush him.

**TANTIA TOPI**, tăn'tê-â tō'pê (c.1819-59). An Indian insurrectionist commander, conspicuous in the Sepoy mutiny of 1857-58. He was born at Bithur, near Cawnpore. He became the chief lieutenant of Nana Sahib (q.v.) in 1857. After the defeat of Nana Sahib by Havelock, Tantia Topi conducted the campaign alone until the flight of his superior into Oudh and Nepal made communication impossible. He then acted under the orders of Rao Sahib, nephew of Nana Sahib. It was due to his generalship alone that the rebellion continued after the capture of Gwalior by Sir Hugh Rose and the death of the Rani of Jhansi, in June of 1858. For nine months he baffled the English in Central India, suffering his first serious reverse at Sikar in January, 1859. The rebels were finally dispersed in March, 1859, and Tantia Topi, who had taken refuge in the jungles of Paron, was betrayed (April 7) to Major Meade by his own friend and late associate Man Singh. He was tried by court-martial at Sipri and hanged there on April 18, 1859.

**TANTRA**, tăn'trâ or tûn'trâ (Skt., system, woof, from *tan*, to stretch, weave). The Sanskrit term for a ceremonial or systematic treatise of any kind. In English, however, the word designates a late class of Sanskrit works which are related to the Puranas (see PURANA), and to the magic literature in general. (See *Atharvaveda* under VEDA.) The Tantras are in the main the sacred works of the worshippers of the androgynous Siva (q.v.), or of Sakti, the female principle itself. (See SAKTAS.) They deal with the creation and destruction of the world, the worship of the gods, the attainment of all objects, magical rites for the acquirement of six superhuman faculties, and four modes of union with spirit by meditation. Prayers to the gods, some few of great beauty, occur at rare intervals. Their place is taken by a condensed form of invocation of the divinity by means of a great variety of honorific epithets, one class, the "thousand-name prayers," forming a division by itself. Numerous other subjects are treated by the Tantras, as the mode of breathing in certain rites, or the language of birds and beasts. The form of the Tantras consists usually of a dialogue between Siva and his wife, the latter asking for information as to the mode of performing various ceremonies, and the *mantras* of prayers to be used in them. The followers of the Tantras consider them as a fifth Veda, and attribute to them corresponding antiquity. This claim is entirely imaginary; they are mentioned in some of the Puranas, and are probably later than the lexicographer Amarasinha (q.v.). No less than sixty-four Tantras are noted by the Hindu commentator Sankara (q.v.). Consult E. W. Hopkins, *Religions of India* (Boston,

1895); Ewing, "The Cārada-tilaka Tantra," in *Journal of the American Oriental Society*, vol. xxiii (New Haven, 1902); *The Tantra of the Great Liberator (Mahānirvāṇa Tantra)*, translated with commentary by Avalon, London, 1913).

**TAN'TUM ER'GO**. The last two stanzas of the hymn *Pange lingua*, which are prescribed to be sung at benediction of the sacrament in the Roman Catholic Church.

**TANZIMAT**, tăn-zē'mât (Ar. *tanzimat*, pl. of *tanzim*, regulation, inf. of second form of *nazama*, to arrange in order). The organic laws in accordance with which the administration of the Turkish Empire is in theory carried on. They were the result of the reform movement introduced by Mahmud II. The organic laws, known as the *hatti sherif* of Gulhane, were promulgated on Nov. 3, 1839, by Mahmud's son, Abdul Medjid (q.v.), soon after his accession. They established the equality of civil rights for all subjects, limited the power of the government officials, guaranteed the free practice of religion, and introduced radical reforms in the administration of finance, justice, and the army. In 1856 the Sultan found it necessary to publish a new ordinance, in which the complete carrying out of the Tanzimat in all respects was commanded. Other attempts in 1868 and 1876 to make the constitution effective were unsuccessful. Consult Engelhardt, *La Turquie et le Tanzimat* (Paris, 1882-84). See TURKEY.

**TAOISM**, tou'iz'm. A system of philosophy (also a sort of religion to-day) in China, the greatest exponent and practical founder of which, Lao-tse (q.v.), is venerated by the educated Chinese second only to Confucius. Just what the word Tao and the philosophy it embodies really mean is very difficult to explain. Lao-tse himself could present no adequate definition, and simply calls it "the way." Confucius acknowledged that he could make nothing of it. Broadly speaking, Tao may be defined as the proper way, the right road, a conduct of life designed to give the greatest individual happiness, contentment, and peace of mind. J. M. Kennedy presents the following definition: "Tao, a word which it is almost impossible to define fully and accurately, refers to 'the way' in which things first came into being out of primordial nothingness, and how, without struggling or striving, the phenomena of nature still continue."

The word Tao was not original with Lao-tse, for the name had been given to many principles of conduct since the time (some say) of Hwang-ti (2750 B.C.). At any event Tao, and also the combination Tao and Teh, were in use centuries before the great philosopher, and emperors were supposed to rule the people with regard to this principle. But it was Lao-tse (or Li-ehr, his proper name, for Lao-tse means "the Old One") who first connected these floating ideas into a very definite system of philosophy by his book, the *Tao-teh-king*, which he is supposed to have written shortly before going into retirement beyond the Pass (a little east of the modern Signanfu, and at that time the western boundary of the federated Chinese states) in 479 B.C., 35 years before the death of Confucius. Now the cultivation of Tao is what leads to the habit, or conduct, or philosophical reasoning, or rule of action, of Teh. Teh, in fact, is virtue. Professor Parker suggests the term "Providence" to signify Tao and "Grace" to signify Teh. Consult also, *Religions of India* (Boston,

*Tao-teh-king*. This book is a very small one, consisting of only 5000 characters, but in it is included all of the philosophical mysticism of Taoism. The great Chinese historian, Sze-ma-t sien, writes of a meeting between Lao-tse and Confucius which was not a very happy one, for the "Old One" was not much impressed with China's greatest philosopher and distinctly reproved him. Confucius in return has nothing to say of Lao-tse's book except the discussion of one passage. It has been contended that the *Tao-teh-king* is not a genuine work of Lao-tse, especially because it is not mentioned by Mencius (q.v.). Professor Giles denounces it as spurious, and cites elaborate arguments in support of his view. Dr. Legge and Professor Parker regard it as genuine.

Lao-tse is opposed to the struggling and striving in human action. "Aim at extreme disinterestedness and maintain the utmost possible calm." Inaction is the secret of the highest human conduct. "Tao is entirely inactive, and yet it leaves nothing undone." Again: "Act with the least possible dwelling on action; employ means with the least possible ado; taste with the least possible dwelling on the savor; make the big as little and the many as few as possible." Also: "One may know the world without ever crossing the threshold; one may discern the Tao of Heaven without ever looking out of the window." In fact, Lao-tse was a recluse himself and meditated in seclusion; finally, like Timon of Athens, some of whose unamiable qualities he seems to have had, retiring from the active world altogether.

Some of his teachings are very Christian in spirit. "He who can overcome other men is strong, but he who overcomes himself is mighty." "It is by bending that we survive, by giving way that we assert. It is by lowliness that we exercise full force." Still more striking is the admonition to "recompense injury with kindness."

He has some curious ideas on the state. "When a great state is conciliatory and deferential to a small state it ends by taking the small state." Historically this is true enough, but the correlative idea that "when the small state is humble and respectful to the great state it captures the great state" is hardly compatible with the teachings of modern world politics. His idea of the size of the state is rather platonic. "My ideal is a series of small states with small populations. Let them possess an army machine of moderate size, but not be too ready to use it. . . . Each state would be within easy sight of the other; the sound of each other's hens cackling would be heard across." He has naturally no conception of the modern spirit of world trade and colonial expansion. "The people of each state would live to a good old age, and would have no movement of intercourse with neighboring states." Naturally, these views were determined by the China of Lao-tse's day. China was then in the feudal period of the Chou dynasty and divided into various powerful principalities frequently at war with one another.

Equally out of place and undemocratic are some of his views on government. "The more weapons of power are intrusted to the people, the more blundering is the government likely to be. The more cunning arts the people learn, the greater the flood of strange objects of luxury." But there is truth in his statement regarding the overabundance of laws. "The more

legal enactments there are, the more thieves and robbers will abound." He is determined against popular government. "The difficulty of governing the people arises from their having too much knowledge." He cautions the autocrat as follows: "He who tries to govern a state with wisdom is a scourge to it, while he who does not try to govern thereby is a blessing." But he gives the King some wholesome advice. "Do not confine the people within too narrow bounds; do not make their lives too weary. For if you do not weary them with life, then they will grow weary of you." He is opposed to militarism. "Those who support and counsel the ruler of mankind under the principles of Tao do not make use of military force to compel the world."

In contrasting Taoism with Confucianism we find most marked the absence of Hsiao (filial piety) in Lao-tse's teachings. Taoism, however, condemns all interference with the natural order of things and thus all statecraft, especially any and every rule by force. It is the practical application of *laissez-faire*, more than that, it has no sympathy with the progress of science or the cultural arts. The doctrines of Confucius are more in the nature of service to society, human intercourse; their spirit is communal. Taoism, however, is individualistic, mystical, adapted to human relationship and, in somewhat aristocratic. Confucius wanted an ideal social order of service to the sovereign, state, and family. Lao-tse, as we have seen, has rather weak conceptions of individual duty to the state and to the community.

The two greatest disciples of Lao-tse and the ablest expounders of Taoism were Lieh-tse and Chwang-tse, the former of the fourth and the latter of the third century B.C. The first is more metaphysical and speculative, the other popular and witty. Especially Chwang-tse is very severe on the literati and even ridicules their great master Confucius. Taoist ethics are best represented in the *Kan-ying-pien* (Book of Rewards and Punishments) of the fifteenth century. In the sixteenth century it was incorporated in the *Tao-chang*, a collection of Taoist scriptures. It contains 212 moral maxims illustrated by stories and references to the history of China. The distribution of this book is deemed a religious duty, and innumerable editions are published at the expense of pious Taoists. Among the great men who were professed Taoists, Chang-liang (died 189 B.C.) deserves special mention for the important part he played in history as a counselor of Liu-pang, founder of the Han dynasty. Taoist legends attribute to him supernatural wisdom and tell of him many marvelous occurrences.

When Buddhism entered China Taoism borrowed from it various forms, ceremonies, and the idea of temples for worship. The "religion" fast degenerated into superstition and mysticism, until to-day it consists of a debased ritual composed of witchcraft, demonology, and hocus-pocus which has not the faintest resemblance to the teachings of Lao-tse. The Taoist priests of the present time claim to be in possession of magic powers, or are engaged in alchemy and other studies. Two thousand years ago one Chang Tao-ling became the recognized leader of the Taoist fraternity. He was said to have compounded and swallowed the elixir of life, whereupon he ascended visibly to Heaven. He bequeathed his secrets to his descendants, thereby establishing a hereditary Taoist papacy. The

soul of each Pope is supposed to pass by transmission into the body of his successor, as with the Dalai Lamas of Tibet. The head of the fraternity is regarded as the vice regent of God on earth and bears the title of the Pearly Emperor of Heaven. His power is considerable among the Chinese masses.

Taoist priests to-day know practically nothing of Lao-tse, and merely attend to the spiritual needs of the people, which are not very high. They tell fortunes, determine lucky and unlucky days, and regulate popular feasts. For divination they use the Kwa, a system of trigrams of broken and unbroken lines which are determined with Shih sticks (see PA-KWA), and for the determination of days they use an astrological device called lo-pan, or table of the net, because it resembles a cobweb, in which certain symbols are arranged in concentric circles around a compass. The temples are ill kept, with cheap images and ornaments. Spiritual deities or patrons are provided for everything under the sun, for all the forms of nature, each organ of the human body, every sense, etc. Each locality has its favorite patrons.

**TAO-KWANG**, tou'kwäng' (1781-1850). The reign title of Mien-ning, the sixth Emperor of the present Manchu dynasty of China. He came to the throne in 1820. The first years of his reign were comparatively tranquil, but disturbances and insurrections soon occurred in Turkestan, in Hainan, in Formosa, and in Kwangtung. In 1834 the privileges of the British East India Company were abolished, and the misunderstandings which then arose, combined with the high-handed proceedings of Commissioner Lin, led in 1839-40 to war with Great Britain, the defeat of the Chinese, and the negotiation of the Treaty of Nanking in 1842. This treaty provided for the opening of Shanghai, Ningpo, Foochow, and Amoy besides Canton to foreign residence and trade, the cession of Hongkong to Great Britain, and the payment of an indemnity of 21,000,000 taels, equal at that time to about \$35,000,000. This large payment in addition to the costs of the war, coming on an impoverished treasury, created much discontent among the people, the secret societies became active, and swarms of pirates harassed the government. Tao-kwang died in 1850 and was succeeded by his fourth son, who reigned as Hien-Fung (q.v.). See H. A. Giles, *China and the Manchus* (Cambridge, 1912).

**TAORMINA**, tã'ôr-mě'nã (Lat. *Taurromenium*). A town and popular winter resort in

the Province of Messina, Sicily, 30 miles by rail southwest of the city of Messina (Map: Italy, E 6). It is majestically situated on a rocky terrace 390 feet above the Ionian Sea, but is overhung by the ruins of the castle (1300 feet above the sea), and again to the northwest by Mola (2080 feet) and by Mount Venerè (2834 feet). The theatre, founded by the Greeks, rebuilt by the Romans, and wrecked by the Saracens, was partially restored in 1748, and is of great interest. The ancient city was named after Mount Toro (ancient Taurus), on whose slope it lay, and was founded by the Siculi in 396 B.C., after the destruction of Naxos, near by, which was the oldest Greek colony in Sicily, having been founded in 735 B.C. Under the Roman Empire it was a city of importance. On account of its strong position it was long able to keep out the Saracens, who finally captured it in 902 A.D., killed the people and burned the buildings. Being resettled, it was, in 962, again captured by the Saracens, from whom it was taken in 1078 by the Normans. Pop. (commune), 1901, 4351; 1911, 4941 (town, 4110). Consult Squillaci, *Taormina attraversi i secoli* (Catania, 1892), and R. H. Bell, *Taormina* (Philadelphia, 1916).

**TAOS**, tã'ôz. See TANOAN STOCK.

**TAOTAI**, or **TAUTAI**, tou'ti'. A Chinese official who has the general supervision and control of the affairs, both civil and military, of a *tac*, or circuit, and is usually styled by foreigners the "Intendant of Circuit"—a circuit consisting of two or more fu or departments. A foreign commissioner of customs ranks with the taotai, and all foreign consuls have the rank of taotai. The taotai is the Chinese official of lowest rank to come in direct contact with foreigners.

**TAPAJOS**, tã-pã-zhôs'. A south tributary of the Amazon, flowing entirely within Brazil (Map: Brazil, F 5). It is formed by the Juruna and Arinos rivers in the northern part of the State of Matto Grosso, flows north and northeastward till it enters the Amazon at Santarem after a course of about 1200 miles. Its headwaters are on a low and flat divide which separates its basin from those of the Paraguay and the Guaporé. The upper course lies on the great Brazilian plateau, from which it descends to the forest plains of the Amazon in a series of falls and rapids which completely obstruct navigation. The last 200 miles only are navigable for large vessels. Near its mouth it expands into a large lake 70 miles long and 12 miles wide, but contracts again just before entering the Amazon.

**TAPARELLO**, MASSIMO. See AZEGLIO, MARCHESE D'.

**TAPE GRASS**, EEL GRASS, WILD CELERY. Popular names for *Vallisneria spiralis*, an aquatic grasslike plant which grows in slow waters, being common from New England to Minnesota and south to Florida and Texas. It is said to be the favorite food of wild ducks. See VALLISNERIA.

**TAPESTRY** (Fr. *tapisserie*, from *tapis*; It. *tappesseria*; Sp. *tapiceria*; Ger. *Tapete*, once meaning tapestry, but wall paper now; Lat. *tapete*; Gk. *rárrns*). In its broad sense any fabric for upholstering furniture, wall, or floor. In another sense, heavy-weight upholstery goods, as distinguished from laces and prints. Specifically (1) primitive tapestries; (2) picture tapestries of the Arras, Brussels, Gobelin, or Aubusson type; (3) Jacquard tapestries that are machine imitations of and developments

from Nos. 1 and 2; (4) tapestry carpets, and rugs that are machine woven with pile formed by an extra set of warp threads printed with colored patterns before weaving; (5) an imitation of No. 4 printed after weaving; (6) tapestry paintings that are painted imitations of No. 2 on canvas or rep; (7) tapestry embroideries that are embroidered imitations of No. 2; (8) tapestry wall paper, i.e., wall paper printed with crossed lines to give the tapestry effect, mostly in imitation of verdure tapestries of the No. 3 variety.

The only real tapestries are varieties 1 and 2. All of these are woven entirely by hand, without shuttle, or drawboy, or Jacquard attachment. All are in plain weave, with weft threads blocked in by colors, and with warp threads entirely concealed but making their position manifest in the form of ribs. Real tapestries are exactly alike on face and back, except for the loose threads on the back that mark the passage of bobbins from block to block of the same color, and except of course that the back is left handed as compared with the face. All are woven back to the weaver, who on most low-warp looms does not see any part of what he has done until the whole is completed. Where two colors appear parallel with the warp threads, open slits are left in the weaving, which are sewed up after the tapestry is completed, but which are an important part of tapestry texture, as they make the cloth less flat and regular than it would otherwise be.

Tapestry is the figured fabric easiest to weave on a primitive bobbin loom (i.e., a loom without a shuttle). Consequently tapestry is woven by most primitive peoples who can weave at all. Among the most interesting primitive tapestries woven to-day are the Oriental kelims which are imported and sold as Oriental rugs and properly regarded as a variety of Oriental rugs. (See RUGS, ORIENTAL.) Other primitive tapestries woven to-day are Navajo blankets and Mexican serapes. Some of these have weft threads that are so large and coarse and soft that the warp threads cannot make their presence felt as ribs, and the surface is flat. The most important ancient primitive tapestries that have been preserved are the Coptics (made in Egypt from the fourth to the eighth century A.D.), of which there are collections in the New York Metropolitan Museum and in several European museums; and the Peruvians (made in South America from the fourteenth to the seventeenth century A.D.), of which there are collections in the Boston Museum of Fine Arts and in the New York Museum of Natural History. There also survive a few examples of ancient Greek primitive tapestries dating from the fifth century B.C. and a few examples of ancient Egyptian primitive tapestries dating from 1500 B.C. In all of the primitive tapestries thus far enumerated, the weft is commonly of wool, the warp of cotton, linen, or wool.

China being the mother country of silk, one is not surprised to find that the weft of Chinese tapestries is of silk, and that Chinese tapestries are much thinner and lighter than all others. The designs of Chinese tapestries are largely decorative, and scenes and figures are usually introduced in such a manner as not to exalt the tapestries from the primitive into the picture class. Chinese tapestries, even those directly copied from the European Gobelin tapestries, do not possess the qualities of construction

or expression that distinguish tapestries as an important separate form of art. Many Chinese tapestries have shadows and supplementary line effects painted on after weaving, somewhat in the manner of the brown enamel on early European stained-glass windows; many Chinese mandarin robes are made entirely of intricately woven and exceedingly beautiful tapestry. In texture, the Saracenic silk tapestries of the Middle Ages did not differ at all from those of China. One of the most important surviving examples is a stole, with Arabic lettering, that was one of the garments buried with the Bishop of Bayonne at the beginning of the thirteenth century, and exhumed about the middle of the nineteenth century. It is now in the Cluny Museum.

Picture tapestries are a higher form of primitive tapestries, and developed from them. We know that the ancient Greeks and Romans had picture tapestries as well as primitive tapestries. In the *Odyssey*, Homer describes the famous picture tapestry that Penelope wove. Andromache, too, wove a tapestry, the shroud that was to envelop the body of Hector. Most wonderful of all was the tapestry in which Helen wove the story of her own tragic life.

About the picture tapestries of ancient Rome we know from the spirited weaving contest described by Ovid in his *Metamorphoses*. Unfortunately, of the elaborate picture tapestries of ancient Greece and Rome, none have survived.

The art of weaving picture tapestries was undoubtedly brought to a higher degree of elaboration, and to greater perfection, in France and in Flanders, in the fifteenth and sixteenth centuries than it had ever attained previously. The revival of the art almost paralleled the development of pictures in stained-glass windows, and the general effect of some of the earliest pieces of tapestry is like that of stained glass of the period, the outlines being accentuated in brown, much as the stained-glass outlines are accentuated by the leads. Examples of this are the three thirteenth-century tapestries preserved in the cathedral at Halberstadt, Germany, perhaps of local manufacture. Two of these tapestries are 3 feet, 7 inches high by about 30 feet long—narrow bands intended to hang above the choir stalls. The first pictures Christ and the Apostles. The second pictures the story of Abraham and Isaac. The third is nearly square, a little higher than wide, with Charlemagne in the centre, on his throne, crowned, sceptre in hand, a rich cushion beneath his feet. In the corners of the tapestry are the four philosophers—Socrates, Plato, Cato, and Seneca. Others of these early tapestries show Byzantine or Saracenic influence, notably the three famous fragments from the church of St. Gereon, Cologne, now shared by the museums of Lyons, Nuremberg, and South Kensington. Large circular medallions on a brownish-blue ground represent, in tones of light ivory, a winged griffin with eagle above and bull below.

Of tapestries made in the fourteenth century, but few have survived. There is only one in the New York Metropolitan Museum, a small Crucifixion, with stars patterning the background. In the Brussels Museum, there is the Presentation of Jesus at the Temple, which attracted great attention at the Tapestry Exhibition in Paris in 1876, and at the Exposition of French Primitives in 1904. It is made entirely of wool, with no silk or metal. The only set of

tapestries surviving from the fourteenth century is the famous Apocalypse at the cathedral of Angers. Originally there were seven pieces showing 90 separate and distinct scenes, 18 feet high with a combined width of 473 feet. Some of the 90 scenes contained more than 25 personages. To-day the height is only 14 feet, and the total width 328 feet. The floriated bands at the top and bottom and the inscriptions with each scene have worn away during the course of 500 years. Of the 90 scenes, 70 remain intact, and there are fragments of eight others, while 12 have entirely disappeared. These tapestries were made for the Duke of Anjou to hang in the chapel of his château at Angers. The cartoonist was Hennequin de Bruges, the court painter of Charles V, brother of the Duke of Anjou. The source of the design was an illustrated manuscript of the Apocalypse, which is now in the public library of the city of Cambrai. The painter followed the manuscript illustrations closely, executing the cartoons on large pieces of canvas the size that the tapestries were to be. The manufacturer of the tapestries was Nicolas Bataille of Paris, who received 1000 francs a piece for them.

From the fifteenth, sixteenth, seventeenth, and eighteenth centuries, hundreds, even thousands, of large tapestries still survive. These divide themselves rather obviously into Gothic of the fifteenth century, Renaissance of the sixteenth century, baroque of the seventeenth century, rococo or classic of the eighteenth century. Only it must be remembered that Gothic overlapped the sixteenth century 15 or 20 years, just as Renaissance overlapped the seventeenth century, and baroque overlapped the eighteenth century. Most of these tapestries were French, or Flemish, or French-Flemish; comparatively few were woven in Italy, or Spain, or England. Up to the last quarter of the fifteenth century Flanders was French; while Flemish was the language of many of the common people, the polite language was French, and the inscriptions for tapestries are always in either Latin or French. After the death and defeat of Charles the Bold in 1477, and the consequent downfall of the Burgundian power, Flanders ceased to be French. By the marriage of Charles the Bold's daughter, Mary of Burgundy, to the Emperor Maximilian, Flanders came under the power of the Hapsburgs; after that tapestries were no longer French-Flemish but French or Flemish. During the whole of the sixteenth century they were nearly all Flemish; after the beginning of the seventeenth century they were either Flemish or French, with the scales constantly inclining more and more in favor of France, until at the end of the eighteenth century tapestry weaving in Flanders was given up altogether.

The first great centre of tapestry weaving in Flanders was Arras, that gave the name of *arras* to tapestries in England, of *arazzi* to tapestries in Italy, of *paños de ras* to tapestries in Spain. During the fifteenth century, however, Arras lost its preëminence in the art of tapestry weaving to Brussels, which remained the chief centre of tapestry weaving as long as the weaving of tapestries continued to be practiced in Flanders. Of tapestries woven at Arras, only one set can be positively identified, the Story of St. Piat and St. Eleuthère at the cathedral of Tournai, Belgium; but as if to make up for our lack of information about other ancient tapestries that may have been woven at Arras,

we not only know that the St. Piat and St. Eleuthère tapestries were woven there, but we also know the exact month and year of their completion, the name of the maker, and the name of the donor. One of the pieces now lost bore the following inscription, which was fortunately copied and preserved in the eighteenth century: "These cloths were made and completed in Arras by Pierrot Fere in the year 1402 in December, gracious month. Will all the Saints kindly pray to God for the soul of Toussaint Prier." This Toussaint Prier, who gave the tapestries to the cathedral of Tournai, was a canon there in 1402, but later became chaplain to the Duke of Burgundy, Philip the Good. As documents in tapestry history, these tapestries are second in importance to the Angers Apocalypse only. The material is wool, without silk or gold. Of the 18 scenes that there were originally, only 15 survive, in four pieces 6 feet, 10 inches high, with a combined width of 71 feet, 8 inches.

The most important early fifteenth-century tapestry in the United States is the Burgundian Sacraments presented to the New York Metropolitan Museum. Of the original 14 scenes, only seven remain, in five fragments, with inscription misplaced. An unusual feature of this tapestry is the brick-wall border with floriation outside. The tapestry was originally about 17 feet high by 38 feet wide, and was fully illustrated and described in the *Burlington Magazine* for December, 1907. Two of the pieces are mounted wrong side out, which illustrates very clearly and obviously the fact that tapestries are exactly alike on both sides. Originally this tapestry contained 14 scenes, an upper row of seven illustrating the seven sacraments in their origin; a lower row of seven illustrating the seven sacraments as celebrated in the fifteenth century.

Of all the hunting tapestries, none surpass in importance and interest the set of four dating from the second quarter of the fifteenth century, and lent to the South Kensington Museum by the Duke of Devonshire. They were discovered some years ago in fragments in Hardwicke Hall, having been cut up for use as window draperies. They were in bad condition, and were restored under the direction of Sir Purdon Clarke. In making the restoration the colors that on the front had faded were copied from the still vivid back. One of the four tapestries is 14 feet by 37; the others are slightly smaller. The material is wool only.

Immensely popular with Gothic tapestry weavers was the story of the Trojan War. Of the original small color sketches, 15 by 22 inches, that served as models for the full-size cartoons, there still survive eight in the Louvre, all in good condition. These sketches were drawn with the pen and colored red, blue, and yellow with water colors. Of tapestries woven from these sketches, there survive three fragments in the South Kensington Museum, seven in the Court House of Issore, France, one in the Spanish cathedral of Zamora, and one in America. In style these Trojan War tapestries resemble the huge Clovis tapestries at Rheims, and the splendid Capture of Jerusalem in the New York Metropolitan Museum.

In the last quarter of the fifteenth century, the influence of the approaching Renaissance begins to make itself felt, although Gothic tapestries continue to be woven through the first

quarter of the sixteenth century. Gradually horizontal effects begin to replace some of the vertical effects that were dominant in earlier tapestries. Hats began to be wider and flatter and lower; shoes to have round instead of pointed toes; a definite sky line appears at the top of tapestries. Most significant of all, tapestries begin to have borders on four sides, instead of none, or at top and bottom only. These late Gothic borders are from 5 to 6 inches wide, usually with flower-fruit motifs. The masterpieces of the late Gothic period are the Mazarin tapestry lent to the Metropolitan Museum by Mr. Morgan, and the pieces that resemble it in the Royal Spanish collection. Especially noteworthy are the Story of the Virgin tapestries that formerly belonged to Philip the Handsome, father of the Emperor Charles V. The Mazarin tapestry, so called because it formerly belonged to the famous Cardinal, represents the best that can be done with gold and silver and silk and wool, to picture many figures elaborately gowned, with flesh and hair that are marvelous in texture and tone. The flesh tints are extraordinary, and represent an intricacy of interweaving that almost passes credibility. Compared with an ordinary tapestry, this one is like the most delicate cloisonné against a parquet floor. In plan the Mazarin tapestry is a triptych, with panels separated by Gothic jeweled columns, and with wings divided by Gothic jeweled arches. The subject is the Triumph of Christ and of the New Dispensation. In the middle panel is shown Christ seated on his throne, right hand upraised, Gospels in left hand, with richly illuminated pages open towards the two groups of worshippers below. One of these groups represents the Church and is headed by the Pope; the other group represents the state and is headed by the Emperor. The Old Empire is represented by Ahasuerus and Esther, in the right wing of the tapestry; the New Empire by Augustus and the Roman sibyl, in the left wing of the tapestry. The Triumph of the Roman church over the Jewish church is also symbolically represented. There are two Latin inscriptions in Gothic letters to help explain the story.

The most famous tapestries in the world are the Acts of the Apostles set at the Vatican, designed by Raphael for Pope Leo X to hang in the Sistine Chapel. These tapestries revolutionized style in tapestry designing and weaving. They not only substituted Renaissance for Gothic; they also substituted Italian for Flemish. Even Flemish painters began to work in the Italian style. By contemporaries and by posterity Raphael's Acts of the Apostles tapestries were praised without end. By engravers, by painters, and by weavers they were copied over and over again. The woven copies are to-day among the chief treasures of the Royal Spanish collection, the Imperial Austrian collection, the French National collection, the Berlin Museum, Hampton Court, the Bauvais Cathedral, the cathedral of Loretto, the Dresden Museum. Of the seven full-size cartoons that are in the South Kensington Museum, having been brought to England on the order of Charles I for the Mortlake Tapestry Works, the Duke d'Aumale said: "they are, together with the Parthenon marbles, England's most beautiful art possession," and "as examples of Raphael's work, unexcelled except perhaps by the Chambers of the Vatican."

The most prolific designer of tapestries in the style of the Italian Renaissance was Raphael's famous pupil, Giulio Romano. His most famous sets were the Story of Scipio, the Fruits of War, the Story of Romulus and Remus, the Grotesque Months, Children Playing. The first and most important set of Scipio tapestries, woven from the designs of Giulio Romano, was for Francis I to hang in the chateau of Madrid. This set was made by Marc Cretif, of Brussels, and in 1797 was burned for the gold that it contained. Of the original small color sketches fifteen are still preserved in the Louvre. Of the Scipio tapestries now in America, woven in Brussels in the sixteenth and seventeenth centuries, some are based upon the designs of Giulio Romano, others upon designs created by other artists, to supplement the series, particularly stories of subordinate characters. Examples of the latter are Sophonisba at the Feet of Masinissa, after Rubens, and Scipio Upbraiding Masinissa. The Conference of Scipio and Hannibal, in the Boston Museum of Fine Arts, is reversed in direction and much modified in details from the designs of Giulio. Of one of the early sets from the original designs, there is an example in the Cincinnati Museum, the Assault on New Carthage, but cut down in size, and with applied and later side and bottom borders. Early Renaissance in every detail of design and execution, and luxuriantly rich with gold, that has been inserted with marvelous skill in plain, basket, and couched weave, is a set of which eight are still in Madrid, the other four in New York. This set has the wide and magnificent compartment borders inspired by the woven pilasters of the original Acts of the Apostles set. Those woven pilasters were not borders in the ordinary sense of the word, there being only seven of them for ten panels, but they were planned to hang between the tapestries and continue the vertical effect of the painted pilasters in the wall above them. The bottom borders of the ten panels were of an entirely different type, being woven imitations of bas-relief. The Acts of the Apostles set, woven a little later for the King of Spain, and still preserved in the Royal Spanish collection, has full side and bottom borders of the compartment type, designed by Giulio Romano, who had helped to create the original seven woven pilasters.

Characteristic of Renaissance tapestries are the very wide borders, 17 to 22 inches, due to the influence of the Italian Renaissance compartment borders. About the middle of the seventeenth century borders began to decrease in width, and towards the end of the eighteenth century disappeared altogether, thus completing the cycle of style in borders, and ending where the fifteenth century began.

The greatest Flemish designer of tapestries in the style of the Renaissance was Bernard van Orley. Among famous sets designed by him were the Hunts of Maximilian, in 12 pieces, now in the Louvre; the Battle of Pavia, presented by the Netherlands to Charles V in 1531 and now in the Museum of Naples; the Life of Christ that was once in the famous Berwick and Alba collection. To this Life of Christ belongs the Dollfus Crucifixion, now in the Metropolitan Museum. Most of Van Orley's tapestry borders are in width transitional, from 10 to 12 inches, wider than late Gothic borders, but narrower than those of the full Renaissance.

## TAPESTRIES

INTERVIEW OF SCIPIO AND HANNIBAL. A RENAISSANCE TAPESTRY AFTER GIULIO ROMANO, WOVEN IN BRUSSELS

BAPTISM. ONE SCENE, MOUNTED WRONG SIDE OUT, FROM THE GOTHIC EARLY FIFTEENTH CENTURY "SEVEN SACRAMENTS," GIVEN TO THE METROPOLITAN MUSEUM OF ART, NEW YORK, BY THE LATE J. PIERPONT MORGAN

## TAPESTRIES

THE SACRIFICE AT LYSTRA. AN ENGLISH MORTLAKE SEVENTEENTH CENTURY TAPESTRY, IN THE FRENCH NATIONAL COLLECTION. REPRODUCED FROM ONE OF THE FAMOUS "ACTS OF THE APOSTLES" TAPESTRIES DESIGNED BY RAPHAEL FOR POPE LEO X.

RINALDO AND ARMIDA. FRAGMENT OF ONE OF THE FAMOUS RINALDO AND ARMIDA SERIES WOVEN IN PARIS IN THE FIRST HALF OF THE SEVENTEENTH CENTURY.

The baroque tapestries of the seventeenth century, like the paintings and the architecture, were sculptural in style. All objects represented on a flat surface were backgrounded with deep shadows in order to make them project or stand out from the picture. Characteristic of the period is the style of Rubens, in whose studio were made many designs for tapestries, notably the Constantine set for the Gobelins at Paris. During the last quarter of the sixteenth century the tapestry industry at Brussels had been almost exterminated by religious wars; and though it was revived again in the first quarter of the seventeenth century by the protecting care of the archdukes Albert and Isabella, it never regained its former glories. Many of the best weavers went to France and to England, attracted by the invitations of Henri IV and James I.

There had been tapestry weaving in Italy in the fifteenth century at Mantua and at Ferrara and in the sixteenth century at Ferrara and Florence. But not until the seventeenth century was there any real transplanting of the industry on a large scale from its Flemish home.

The tapestry works of the Gobelins were established, as the inscription over the entrance says: "April, 1601, Marc de Comans and François de la Planche, Flemish tapestry weavers, install their workrooms on the bank of the Bièvre." The works retained the name of Gobelins from the dye works established there in 1440 by Jean Gobel. Both manufacturers came from Flanders—Planche from Oudenarde, Comans from Brussels. Among important sets woven at the Early Gobelins were the Story of Artemisia; the Story of Diana; the Story of Constantine, designed by Rubens; the Story of Clorinda and the Story of Theagenes and Chariclea, designed by Dubois; the Story of Gombaut and Mace. In 1662 Louis XIV bought the Gobelins plant, and in 1667 the Furniture Factory of the Crown at the Gobelins was formally organized as a state institution. To the Gobelins were also transferred the other tapestry works at that time active in the city of Paris, as well as the works that had been established at Maincy by Fouquet, the unfortunate Minister of Louis XIV. From Maincy also came Charles Lebrun to head the Gobelins, and to act as dictator and creator of the style of Louis XIV.

At the Gobelins high-warp and low-warp looms were operated side by side until the nineteenth century. Since then high-warp looms only have been employed at the Gobelins. The high-warp loom is so called because the warp threads are stretched vertically, in contrast to the horizontal plane that they occupy in the low-warp looms. In the high-warp looms it is necessary to pull by hand the lisses or loops of cord that shift the position of the warp threads to form the new shed; in the low-warp looms this is done more rapidly and easily by treadles. In other words, the high-warp is hand-work exclusively, while the low-warp is hand-and-foot work. The principal reason for using the slower and more expensive high-warp process at the Gobelins is that it enables the artist director to watch the work of the weaver more closely.

The most important set of tapestries created at the Gobelins during the reign of Louis XIV was the Story of the King, in 14 huge tapestries, picturing and celebrating the more important events of the early part of the reign of Louis

XIV, among them his coronation, his marriage, and his victories in war. Especially interesting is the one that pictures Louis XIV visiting the Gobelins. The set most often woven at the Gobelins during this period was the Royal Residences, picturing the 12 palaces that the King liked best. The Story of Alexander was in special favor on account of the allusions found in it to the glories of Louis XIV. About the only set with much everyday human interest was the Child Gardeners. All of these sets were designed by Lebrun, although the details were worked out by the numerous artists employed under him in the royal studios. As the King grew older, the opportunities for glorification became fewer. So, instead of the Story of the King, we have the Story of Moses; the Indies; the Triumphs of the Gods; the Portières of the Gods; the Old Testament; the New Testament; the Metamorphoses of Ovid; together with numerous reproductions of sixteenth-century designs, such as the Story of Scipio, the Fruits of War, the Hunts of Maximilian, the Months of Lucas.

Of Louis XV Gobelin tapestries the Don Quixote series in 28 scenes, designed by Charles Coppel, were the most celebrated. Other important Louis XV sets were: Coppel's Opera Fragments; the Story of Esther, designed by De Troy; the Hunts of Louis XV, designed by Oudry. During the reign of Louis XV many of the old designs were reproduced, and many furniture coverings and portrait tapestries were executed.

In 1664 the tapestry works at Beauvais were established as a private institution, under royal protection and encouragement. Among important pieces woven at Beauvais in the reign of Louis XIV were: Children Playing; the Conquests of Louis the Great; a reproduction of Raphael's famous Acts of the Apostles, signed by the proprietor of the Beauvais Works, Béhagle, now in the Beauvais Cathedral; numerous Chinese and other grotesques, designed by Bérain. In the reign of Louis XV the selection of Oudry as artistic director of the Beauvais Works quickly brought great commercial success. Oudry not only supplied important original designs of his own, but also supplemented his own efforts by those of Boucher. It was for Beauvais and not for the Gobelins that Boucher did his best work and the majority of his work. Among the sets designed by Boucher for Beauvais were the Italian Fêtes; the Story of Psyche; the Chinese set; the Loves of the Gods; Opera Fragments; the Noble Pastorale. One result of the success of Oudry at Beauvais was that the painter Dumons was sent to Aubusson to try to revive and develop the industry there. Aubusson is a small town in the mountains of Auvergne, 250 miles south of Paris, where tapestries had been woven since the sixteenth century in designs that were crude, texture that was the coarsest, with dyes that were bad. As a result of the efforts of Dumons and his successor Juliard at Aubusson, many exceedingly attractive tapestries were woven there during the latter two-thirds of the eighteenth century. Today the commercial centre of tapestry production—rugs and furniture, coverings as well as wall panels—is Aubusson.

The establishment of the Gobelins inspired the English to activity at Mortlake, near London. Here in 1619, in the reign of James I and with the special encouragement of the then Prince of Wales, who later became King as Charles I,

were set up looms to be operated by weavers imported from Flanders. In planning the enterprise the French example was closely followed, and one of the shop managers at the Early Gobelins, Philip de Maecht, was imported to act as superintendent of the new works. While the Mortlake Works continued in existence until 1703, they were successfully active for only about 15 years. Among the most important sets woven there were: the Story of Venus and Vulcan; the Acts of the Apostles from the Raphael cartoons that are preserved to-day in the South Kensington Museum; the Story of Hero and Leander, designed by Francis Clein, who was the artistic director. The tapestry works founded at Merton, near London, in 1881 by William Morris are still operated and in 1915 produced a large historical tapestry commemorating the coronation of King George V, entitled "The Arming of the King." The most important tapestries produced at Merton were from the designs of Burne-Jones, with foliage, flowers, and borders designed by Morris. The Royal Windsor Tapestry Works, established in 1876, lasted only 10 years, but sent their superintendent to become the head of the first tapestry works established in America. The looms were set up in New York City on Fifth Avenue in 1893, but were soon moved to Williamsbridge. The most important tapestries woven there are in the style of the French eighteenth century. Since then three other tapestry plants have been established in New York City.

The most important collections of ancient tapestries in the world are the Royal Spanish collection, the Imperial Austrian collection, the Royal Swedish collection, the French National collection, the Royal Belgian collection. The most important public collections in England are those at the South Kensington Museum and at Hampton Court. The English private collections are very rich. The most important public collections in the United States are those at the New York Metropolitan Museum and the Boston Museum of Fine Arts. The private collections of New York and Boston are very rich. See EMBROIDERY.

Hunter, *Tapestries: Their Origin, History, and Renaissance* (New York, 1912), containing a bibliography; W. G. Thomson, *Tapestry Weaving in England from the Earliest Times to the End of the Eighteenth Century* (ib., 1915).

**TAPEWORM.** A name for any worm of the group *Cestoda*, but popularly used for the *Tæniidae* or the *Bothriocephalidae*. Nearly 200 species of cestoid worms have been described, of which the majority fall into one of the two families just named. (See *CESTODA*.) These worms have no intestine and are without cilia, but have testes and ovaries in each segment, together with frequent yolk glands. They belong to the order Polyzoa or segmented individuals. They are all endoparasites and secure nutrition from the di-

gestive tract of the host in which they live, absorbing digested food through their body walls.

**Tænia.** A *tænia* consists of a scolex or head and detachable segments or proglottids. Within the scolex is the brain; on the outer surface of

TAPEWORMS.

1, *Tania saginata*; 2, segment of *Tania solium* (showing generative organs): u, uterus; t, testes; o, ovary; d.p.o., detached portions of ovary; y.g., yolk gland, s.g., shell gland, r.sem., receptaculum seminis; v.d., vas deferens; g.p., genital papilla; clo., cloaca; c.p., cirrus pouch; 3, lidded ova of *Bothriocephalus latus*.

the scolex are four sucking disks as well as a ring of hooks. Fixation is secured through the suckers and hooks. In each proglottid is an albumin gland, and a uterus and a vas deferens end in openings on the side of the proglottid. New proglottids grow behind the head, by division of its posterior part. The farther from the head, the larger is the proglottid. The distal proglottids separate from time to time and are excreted with the feces of the host. But the

TAPEWORMS.

a, head of *Tania solium*; b, apical surface and circle of hooks of *Tania solium*; c, hooks of *Tania solium*—larger, anterior; smaller, posterior.

head must be removed to secure freedom from the parasite.

The embryonic stages of tapeworm are hydatids (measles, cysticerci) or *cysticercoidi*. When a *Tænia ovium* with mature embryo is swallowed and reaches the human intestine, it migrates through the blood vessels or lymphatics into the tissues and develops into a hydatid. Both

in man and in the pig the embryo of *Tania solium* becomes a measle; while the embryo of *Tania saginata* becomes, similarly, a measle in the cow. When a cysticercus is ingested by a man, it develops in his intestine into a complete tania. In the human digestive tract a *Cysticercus cellulosæ*, or bladder worm, obtained from

BLADDER WORMS OF PIG.

a, *Tania solium* (evaginated head); b, *Tania solium* (invaginated head); c, *Cysticercus cellulosæ* (head formation completed).

measly pork, becomes a *Tania solium* in six to ten weeks. The *Tania canina* develops in man from a cysticercoid of the cutaneous parasites of the dog. *Tania solium* was so named by Linnaeus because it is generally found alone; but in many instances two or three are found together, and in rare instances as many as 30 or 40 have been expelled from one patient. The full-grown tania or strobila is from 10 to 35 feet in length, and may consist of from 800 to 1000 proglottids. The sexually mature proglottids begin at about the four hundred and fiftieth segment. The breadth of the worm is about  $\frac{1}{2}$  of an inch at the widest. The head is very small and globular or pear-shaped, is about the size of a small pinhead, and is dark with pigment. The crown of hooks numbers about 22 to 28 in each double row. The neck is very narrow and about  $\frac{1}{2}$  of an inch in length, and merges into the wider, segmented part. The impregnated eggs, when discharged into the intestine, do not mature there. They require the second host; such as, e.g., the pig, who eats the expelled proglottids or the ova. The exception to this general rule is met when a cysticercus is found together with a tapeworm in a human digestive tract. This is necessarily a source of grave danger, for the cysticercus may traverse the body as it does in the hog and cause similar lesions; hence the imperative necessity of securing the expulsion of the entozoa as soon as their presence is known. When fully mature the measle resembles a pea or a small kidney bean, being about  $\frac{1}{3}$  of an inch in diameter. Its great vesicular portion consists of a caudal extremity, inflated like a bladder, while the head, neck, and body may be drawn out in vermiform style.

The great source of tapeworm is measly pork, eaten uncooked or but partly cooked. Pork, ham, bacon, and sausage should always be very thoroughly cooked. It is also possible to ingest the embryo of the tapeworm with lettuce or other uncooked green food which has grown where a filthy stream flows over it, or which has been watered with liquid manure. Thorough washing will prevent danger from these vegetables.

*Tania saginata* (or *mediocanellata*) has no circle of hooklets and is about 25 feet in length. In its case cattle instead of hogs are the intermediary hosts. It is transmitted through imperfectly cooked veal or beef. *Tania echino-*

*coccus* is, in its larval condition, probably more fatally injurious to the human race than all the other species of entozoa put together. In its mature (strobila) condition, in which it is found only in the dog and wolf, it seldom exceeds  $\frac{1}{4}$  of an inch in length, and develops only four segments, including that of the head. The final segment, when sexually mature, equals in length the three anterior ones, and contains as many as 5000 eggs. The proscœx or embryo forms large proliferous vesicles, in which the scolices or larvæ (known also as acephalocysts, echinococci, echinococcus heads or vesicles, pill-box hydatids, etc.) are developed by gemmation internally. The eggs develop in their interior a six-hooked embryo, and these embryos are introduced into our bodies with food or water into which the eggs have been carried. It finds its way into the liver, and later is carried by the blood current to other organs, including the lungs, the kidneys, the brain, and the bones. It grows slowly, many months elapsing after the ingestion of tapeworm eggs or embryos before the echinococci appear.

In some countries in Europe hydatids are very prevalent. It is said that the disease is endemic in Iceland to such an extent that one-sixth of the population suffer from it. The cause may be found in the great number of dogs harbored by the Icelanders. *Tania saginata* is common all over the world.

The presence of a tapeworm in the intestines is made certain only by finding pieces of the entozoön in the dejecta, resembling flat segments of macaroni. But in most cases it gives rise to a series of anomalous symptoms, including vertigo, noises in the ears, itching of the nose and anus, ravenous appetite, dyspepsia, colic, palpitation, syncope, and emaciation. In the treatment of tania prophylaxis is important. All meat must be so thoroughly cooked that the centre of each piece is subjected to great heat. Beef is the principal host of the entozoön. Rare beef must therefore be avoided. The medicinal treatment consists in causing the patient to fast for 24 hours and then administering the oleo-resin of *Filix mas* (male fern), which must be followed by a brisk calomel purge. Santonin is also a reliable anthelmintic. The head must be sought in the excrement of the patient and medication must be repeated till the head is evacuated.

Tapeworms, although rare among horses and cattle, are common in dogs and sheep, causing irritability of the bowels and an unthrifty appearance. For dogs no remedy answers so well as powdered areca nut, of which 30 grains suffice for a dog weighing about 20 pounds. It is best given after 10 or 12 hours' fasting, in a little soup or milk, and should be followed in a few hours by a dose of castor oil. Neither areca nor any of the approved remedies used in men prove effectual in sheep; and one of the best prescriptions for them consists of 40 drops of oil of turpentine, a dram of powdered green vitriol, and an ounce of common salt, given mixed in a little milk or gruel, or, where their bowels are confined, in linseed oil. A daily allowance of linseed cake and sound dry food should likewise be given with the grass or roots, and pieces of rock salt left within the animal's reach.

Among other varieties of taniæ are *Tania cucumerina*, which infests the dog and cat, and whose cysticercus is harbored by the flea; *Tania nana*, which is the smallest tapeworm found in

man, and which is frequent in Egypt and Sicily; and *Tania diminuta*, first seen in Italy, rarely found in man. The last named infests rats and mice, and its cysticerus inhabits caterpillars and certain of the Coleoptera. The largest tapeworm, rare in America, but common in central and eastern Europe, is *Bothriocephalus latus*. It is sometimes 25 feet long, nearly an inch broad, and may have 4000 joints. See PARASITE.

Consult M. G. C. Braun, *Animal Parasites of Man* (3d ed., trans. by Pauline Falcke, New York, 1908), and "Worms," in Gould and Pyle, *Cyclopedia of Practical Medicine and Surgery* (Philadelphia, 1912).

**TAPIOCA**, tãp'f-ô'ká. See CASSAVA.

**TAPIR**, tã'për (Sp. *tapiro*, from Tupi Brazilian *tapyra*, tapir). A tropical ungulate mammal of the family Tapiridae, allied to the horses and rhinoceroses. It has a bulky form, with moderately long legs—the front feet four-toed, the hind feet three-toed. The tapir has thick skin, short hair, small tail, thick neck, short ears, small eyes, elongated muzzle; the nose is prolonged into a short, flexible proboscis; it has 6 incisors, 2 canine teeth, and 14 molars in each jaw. The family includes only five living species, with a peculiar geographical distribution, as two species are found in South America, two in Central America, and one in the

DENTITION OF A TAPIR.

Malayan region. The best known is the American tapir (*Tapirus americanus* or *terrestris*), about the size of a donkey, and common throughout the wooded parts of South America east of the Andes. Its color is uniform deep brown, but the young (as with the other species) are beautifully marked with yellowish fawn-colored stripes and spots. The skin of the neck forms a thick rounded crest on the nape, with a short mane of stiff hair. The tapir inhabits deep forests, and delights in plunging and swimming in water. It feeds chiefly on young shoots of trees, fruits, and other vegetable substances, and sometimes commits great ravages in cultivated grounds. It is inoffensive, never attacking man; but when hard pressed by dogs, shows great cunning, and if brought to bay makes a violent resistance and inflicts severe bites. It is easily tamed. Its hide is useful and its flesh is eaten.

The hairy tapir (*Tapirus roulini*) occurs only on high levels on the Andes, up to 7000 or 8000 feet. The skin is uniformly covered with hairs an inch long. There are white marks on the head and the sides are bluish hazel instead of brown. The hog tapirs of Central America (*Tapirus bairdi* and *Tapirus dowi*) are smaller than the other species, and differ from them in having the nasal septum ossified. They are brownish black above, dirty white on the throat and chest, and somewhat rufous on the head.

The Malayan tapir (*Tapirus indicus*) is found in the Malay Peninsula, Java, Sumatra, and other large islands. It is larger than the

American tapir, and its proboscis is rather longer in proportion. The neck has no mane. The color is glossy black, except the back, rump, and sides of the belly, which are white. The colors do not pass gradually one into the other, but the line of separation is marked, giving the animal a very peculiar appearance. The habits of this species are similar to those of the American tapir, and it is equally capable of domestication. The young are striped and spotted as in that species.

Fossil tapir-like forms are known from the Eocene onward, and most of them have been placed in the family Lophiodontidae; but many species are hardly separable from the modern family Tapiridae.

Beddard, "Mammalia," in *Cambridge Natural History*, vol. x (New York, 1902); and general works. See Plate of TAPIRS AND HIPPOPOTAMUS.

**TAPIR TIGER**. See JAGUAR.

**TAPOTEMENT**, tã'pôt'män'. See MESSAGE.

**TAPPAN**, ARTHUR (1786-1865). An American merchant, philanthropist, and reformer, the brother of Benjamin and Lewis Tappan, born at Northampton, Mass. He entered business in Portland, Me., removed to Montreal, Canada, and after the War of 1812 established himself in the importing business in New York City. In 1827 he associated with himself his brother Lewis in the publication of the *Journal of Commerce*. He was largely interested in various religious, educational, and philanthropic institutions. It is as an Abolitionist, however, that he will be longest remembered. He became interested in the American Colonization Society at its organization, but having become convinced that the society was being used by the proslavery party to rid the country of free negroes, in order to establish slavery more firmly, he withdrew from it. In 1830 he paid a fine which secured the liberation of William Lloyd Garrison from imprisonment in Baltimore, and the acquaintance which followed led to Tappan's identifying himself completely with the Abolition cause. In 1833 he was one of the organizers of the New York Antislavery Society and of the American Antislavery Society, of both of which organizations he became the first president. In 1840 he became president of the New American and Foreign Antislavery Society, which was organized by those antislavery men who disagreed with the Garrison party, and believed in carrying the slavery question into politics and forming a political party for that purpose. He was therefore much interested in the Liberty, Free Soil, and Republican parties. He spent the latter years of his life in retirement in New Haven. Consult Lewis Tappan, *The Life of Arthur Tappan* (Boston, 1871).

**TAPPAN**, LEWIS (1788-1873). An American merchant and reformer, brother of Arthur and Benjamin Tappan, born in Northampton, Mass. He became largely interested in cotton manufacturing and calico-print works in Boston, but in 1827 he removed to New York City. Thereafter his career was closely identified with that of his brother Arthur. In 1827 they established together the *Journal of Commerce*, of which Lewis Tappan became the sole proprietor in 1829. In 1833 he was one of the organizers

TAPIRS AND HIPPOPOTAMUS

1. AMERICAN TAPIR (*Tapirus Americanus*).

2. MALAYAN TAPIR (*Tapirus Indicus*).

3. HIPPOPOTAMUS (*Hippopotamus amphibius*).

of the New York (City) Antislavery Society. The firm of Tappan & Co. failed for upward of \$1,000,000 in the financial crisis of 1837, and although they afterward paid their indebtedness, Lewis Tappan retired from the firm and in 1841 established Tappan's Mercantile Agency, one of the earliest and best-known organizations of this kind in the country. With his brother he was one of the organizers of the American and Foreign Antislavery Society, and wrote and spoke in favor of a more rational and conservative attitude on the part of the reformers. He published a *Life of Arthur Tappan* (1871).

**TAPPAN BAY**, or **TAPPAN ZEE**. An expansion of the Hudson River, in New York, lying immediately north of Irvington. It is about 11 miles long, and over 3 miles wide at the widest point.

**TAPPEN**, **FREDERICK D.** (1829-1902). An American financier, born in New York City. He graduated at New York University in 1849, and in 1850 became a clerk of the National Bank of New York, of which in 1857 he became cashier and in 1868 president and director. During the great loans in 1873 and 1874 he was chairman of the loan committee. In 1896 he induced the New York banks to loan \$20,000,000 in gold to the United States. In May, 1901, he formed a pool of \$20,000,000 for loans and broke the 60 per cent and 75 per cent rate for call money. Again in the last week of June his efforts to preserve the credit of a tottering clearing-house bank succeeded in calming the market, although the bank, as he had predicted, failed.

**TAPPERT**, *táp'ért*, **WILHELM** (1830-1907). A German writer on music, born at Ober-Thom-aswaldau, near Bunzlau, Silesia. After teaching for several years, he studied music (1856-58) under Kullak and Dehn in Berlin, where he settled permanently in 1866, and became professor of the history of music at the new academy. His name is favorably known in the musical world through numerous contributions to periodicals and the following publications: *Musik und musikalische Erziehung* (1867); *Musikalische Studien* (1868); *Das Verbot der Quintenparallelen* (1869); *Wagner-Leuikon* (1877); *Richard Wagner, sein Leben und seine Werke* (1883); *Wandernde Melodien* (1890); *Sang und Klang aus alter Zeit* (1906).

**TAPS**. See **BUGLE AND TRUMPET CALLS**.

**TAPTI**, *táp'té*. A river of the Bombay Province, British India (Map: India, C 5). It rises in the mountains of the western part of the central provinces, and flows westward, emptying into the Gulf of Cambay, 160 miles north of Bombay, after a course of about 450 miles. The greater part of its course is followed by a railroad, but the river is unnavigable above Surat, a few miles from its mouth.

**TAPUYA**, *tá-pō'yá* (alien). A collective designation for a group of tribes holding an extensive area in eastern Brazil, constituting a distinct stock, and apparently more ancient in occupancy than any of the surrounding tribes. Their general territory extends from lat. 5° to 20° S., and from the Atlantic coast inland to the Xingu River. They are sometimes also known as *Cren* or *Gueren*, the Ancient People. The Tucano (q.v.) and several other tribes upon the Uaupes and Yapurá on the Brazil-Colombia border are also thought to be of the same connection. The Tapuya tribes, among which the Botocudo (q.v.) are the most noted and typical, have every characteristic of an ancient primitive

race. They are believed to have raised the numerous shell mounds along the adjacent Atlantic coast, and it is held that skulls and other human bones found in caves within their territory, in connection with bones of extinct animals, are of the peculiar type belonging to this people. In physique they are of middle stature, with long arms and short legs, broad faces, small deep-set eyes, retreating foreheads, and projecting lower jaws. Their features are frequently disfigured by labrets in the lower lip. Their culture is low. In their native forests they go naked and have only brushwood shelters. They have no tribal organization, do not possess dogs, build no canoes, make no pottery. Before interfered with by the Brazilian government they were cannibals. But they are skillful hunters with the bow and arrow, make polished stone axes, and weave baskets of rushes. The men have but one wife at a time. Their language, of which specimens have been published by Ehrenreich, is difficult in its phonetics, with a marked tendency to simple word forms rather than agglutination. The Indians of Tupi descent about Pará and on the lower Amazon are incorrectly called Tapuya. Consult J. J. von Tschudi, *Reisen durch Südamerika*, vol. ii (Leipzig, 1867), and D. G. Brinton, *The American Race* (New York, 1891).

**TAR** (*AS. tearo, tearu*, Icel. *tjara*, Ger. *Teer*). A term applied to the oily, dark-colored products obtained in the destructive distillation of peat, wood, coal, bones, and other materials of organic origin. Bone tar is described under **DIPPEL'S ANIMAL OIL** (q.v.). Coal tar is likewise described in a special article. (See **COAL TAR**.) Wood tar is commonly made from the roots and wood of various trees such as the beech and pine. Tars from these sources are not identical, hence it is necessary to refer to them as pine and beech tar. In the old process wood was heaped into a conical stack depressed at the centre, covered with earth, and fired. The tar condensed and ran to the centre of the pile. The operation is now more economically conducted in retorts. By distillation the crude tar is separated into a number of light oils used as solvents for varnishes; creosote oil containing cresols and guaiacol and used as a preservative; and a residue of pitch employed as a waterproofing compound. In doses of one or two grains pine tar is considered a good remedy in diseases of the mucous membrane of the respiratory passages. Tar soap consists of a good grade of tallow soap heavily impregnated with tar and containing sufficient alkali to make the combination soluble in water. See **ACETIC ACID**; **ACETONE**; **METHYL ALCOHOL**; **NAVAL STORES**; **WOOD DISTILLATION**.

**TARA**, *tá'rá*. A hill in County Meath, Ireland, about six miles east of Trim and nearly the same distance southeast of Navan. It is about 500 feet in height and is noted as the site of the palace of the ancient kings of Ireland. It was here that St. Patrick began his great apostolate by preaching to King Laoghaire or Leary in 432. The site was finally abandoned in 565 on account of a curse pronounced against the reigning King by St. Ruadhan. The lines of the ancient palace may still be traced in the mounds and earthworks which crown the summit of the hill. The place is the theme of one of Thomas Moore's popular ballads and remains a focus and rallying point for Irish national aspiration. Here O'Connell, the liberator, held

the greatest of his monster meetings during the Repeal agitation, and here also some 40 years later Parnell erected the monument, which now stands out prominently above the landscape, to the memory of the Croppy insurgents who fell in an engagement near by during the rebellion of 1798.

**TARA.** See TARO.

**TARABULUS**, tã-rã'bûû-lûûs. A town of Syria. See TRIPOLI.

**TARAFÄ**, tã-rã'fã (Ar. *Tarafa* 'Amr ibn al Abd al Bakr) (c.560). An early Arabian poet. He lived at the court of the King of Hira in northeastern Arabia. In consequence of his satires on royalty, the King had him put to death. He ranks as one of the six great pre-Islamic poets of Arabia, and is the author of one of the seven *Mu'allakât* (q.v.), or exalted poems, of that period, which remain the classic models of Arabic poetry. The Arabic text is in Ahlwardt, *Diwans of the Six Ancient Arabic Poets* (London, 1870); there are translations by Rückert, in *Sieben Bücher der morgenländischen Sagen und Geschichten* (Stuttgart, 1837), and by Vandenhoff, *Nonnulla Tarafæ Carmina* (Berlin, 1895).

**TARA** (tã'rã) **FERN** (*Pteridium aquilina esculenta*). A species of bracken (q.v.), the rhizome of which was one of the principal articles of food of the Maoris before the British settlement of New Zealand. This fern is also distributed in Australia, Japan, and the Hawaiian Islands. In Japan the cut rhizomes are macerated to remove the starch.

**TARAHUMARI.** See TARUMARI.

**TARAI**, tã-rã', or **TERAI**. A low, moist forest belt stretching along the southern base of the Himalaya nearly throughout their length, from Assam in the east to the Punjab in the northwest. In spite of its unhealthy nature, it is densely populated by tribes who seem to be immune from malarial diseases.

**TARANTELLA**, tã'rãn-tel'ã (It., tarantula). An Italian dance, written in  $\frac{3}{4}$  time, constantly increasing in speed, and alternating between the major and minor modes. It is accompanied by castanets and a tambourine. During the Middle Ages the dancing of the tarantella was thought to cure a form of insanity induced by the bite of the largest of European spiders, the *Lycosa tarantula*. From the fifteenth to the seventeenth century a peculiar nervous disease called tarantism existed in Italy, said to have been cured by this music. Of the many songs used for this but few exist. Specimens are given in Jones, *Maltese Melodies* (London, 1805); Smith, *Musica Antiqua* (ib., 1812); Mendel, *Lexicon* (Berlin, 1870-83). The tarantellas written by modern composers bear little resemblance to their prototypes in form or rhythm. They are written in  $\frac{3}{4}$  or  $\frac{5}{8}$  time and, owing to their rapidity, became favorites for solos. See DANCING MANIA.

**TARANTISM**, tã'rãn-tiz'm. A dancing mania supposed to be due to the bite of a spider, the tarantula (q.v.), and especially prevalent at Taranto in Apulia, Italy. The disease was a form of contagious emotional or hysterical excitation. The gesticulations, contortions, and cries somewhat resembled those of St. Vitus's dance and other epidemic nervous diseases of the Middle Ages. The victims were supposed to have a passion for bright colors, music, and the dance, and tunes called *tarantella* were composed for their cure. To these the patient

danced until exhausted, and although sufferers were subjected to other methods of treatment, such as burial up to the neck in earth, none was so successful as the tarantella (q.v.). Not only dancing but catalepsy was a symptom, and all classes, ages, and both sexes appeared to be affected. The disease spread over Italy and southern Europe, and affected large numbers of people.

**TARANTO**, tã-rãn'tõ (Lat. *Tarentum*; from Gk. *Tápas*, *Taras*). A town of south Italy, in the Province of Lecce, at the northern end of the Gulf of Taranto (Map: Italy, F 4). It is situated on a rocky islet, formerly an isthmus, between the Mare Piccolo (little sea), an extensive harbor on the east or landward side of the town, and the Mare Grande (great sea), or open gulf, on the west. The harbor, one of the finest in Italy, can be entered safely by the largest vessels. The principal buildings are a cathedral, dedicated to St. Cataldo; a fine episcopal palace; a castle and fortifications, erected by Charles V; and two hospitals. The streets are as narrow and dark as those of an Oriental city. Taranto has manufactures of velvets, linens, and cottons, and carries on some commerce in wheat, oats, and olive oil. The Mare Piccolo is famous for its shell fish, and a considerable portion of the population derives its subsistence from the oyster and mussel fisheries. Pop., 1912, according to Baedeker about 50,000.

Ancient Tarentum was one of the most splendid cities of Magna Græcia. It was founded, according to tradition, about 707 B.C. by the Parthenians, a body of Laconian youth. It rapidly grew in wealth and power, extending its trade even to the Po, and supplying much of southern Italy with pottery. It steadily reduced its Messapian neighbors till 473 B.C., when a bloody defeat was followed by the fall of the aristocratic government and the establishment of a pure democracy. About 400 B.C. Tarentum appears as the leading Greek city in Italy. When in 281 B.C. the Tarentines came into collision with Rome, they invited to Italy Pyrrhus (q.v.) of Epirus. After his departure his general, Milo, surrendered the town to the Romans, 272 B.C., who treated it leniently. During the Second Punic War it was captured by Hannibal, with the exception of the Acropolis. When in 209 B.C. it was retaken by the Romans, it was sacked, and 30,000 of the inhabitants were sold into slavery. Later it was the seat of a prosperous Roman colony. Under the Empire it was quite overshadowed by Brundisium, on the Adriatic, but rose again during the Gothic wars, which left it in the hands of the Byzantine Empire. It was captured in 661 A.D. by the Lombards, and later passed into the hands of the Saracens, who sacked it in 927, and of the Greeks, from the latter of whom it was wrested by Robert Guiscard, the Norman, in 1063. Later it shared the fortunes of the Kingdom of Naples. Few relics of the classic Tarentum are extant, the chief being bits of an amphitheatre and traces of a Doric temple, which from its form must be one of the early monuments of that style. Consult K. Baedeker, *Southern Italy* (16th Eng. ed., Leipzig, 1912), and the article "Tarentum" in Friedrich Lübker, *Reallexikon des klassischen Altertums*, vol. ii (8th ed., Leipzig, 1914).

**TARANTO, DUKE OF.** See MACDONALD, E. J. J. A.

**TARANTULA**, tã-rãn'tã-lã (from It. *taran-*

*tola*, *tarantella*, from *Taranto*, Lat. *Tarentum*, a city in southern Italy, where the spider is common). A famous species (*Tarantula fasciventris*) of European wolf spiders (Lycosidae); its bite was supposed to be fatal or to be followed by serious symptoms. As a fact the bite of this spider is not dangerous. The name

TRUE TARANTULA.

"tarantula" is generally applied in the United States and elsewhere to certain of the large bird spiders, or so-called American tarantulas of the family Theraphosidae. These are large, hairy spiders occurring in the southwestern United States, Central America, and South America, which possess large, hard polished fangs which move vertically and are thus used to pin down their prey. They feed upon insects and all sorts of small animals. *Anane hentzii* is a large species of this group which has the most northern distribution of all of the so-called American tarantulas. It has a bite which is painful but not dangerous, and never fatal, so far as accurate records go. These creatures are nocturnal, hiding during the day in long silken tubes in underground crevices, etc. Some Central American species are occasionally brought north on board vessels containing tropical fruit.

**TARANTULA KILLER.** A large and conspicuous wasp (*Pepsis formosa*), common in the southwestern United States and in Central America, which preys especially on tarantulas (q.v.). It is more than 2 inches long. The head, thorax, abdomen, and long, spiny legs are black, while the wings are bright reddish brown with black spots at the tips. It stings the spider, the result of the stinging being complete paralysis, deposits an egg upon it, then buries it in a hole 5 inches deep after the manner of other mud wasps (q.v.).

**TARAPACÁ**, tã'rá-pá-kã'. A province of north Chile, bounded by Taena on the north, from which it is separated by the Camarones River, Antofagasta on the south with the Loa River as the dividing line, Bolivia on the east, and the Pacific on the west (Map: Peru, D 8). Its area is 18,125 square miles. The coast land is occupied by a mountain range rising to 6000 feet, and the eastern part belongs to the region of the Bolivian Andes. The interior is an elevated arid plain known as Pampa de Tamarugal. The wealth of the province consists chiefly in the immense deposits of nitrate, which are worked on a very extensive scale. Agriculture is carried on to some extent along the rivers, and there are silver mines near the capital, Iquique (q.v.). There is a railway line connecting the capital with Pisagua, the chief sea-

port, and the interior. Pop., 1912, 119,714. Tarapacá was taken by Chile from Peru in 1880 and was formally ceded in 1884.

**TARARE**, tá'rãr'. A manufacturing town in the Department of Rhône, France, at the foot of Mont Tarare, 20 miles northwest of Lyons (Map: France, S., J 3). In 1756 the manufacture of muslins, for which it has since become famous, was introduced from Switzerland. The chief products of its mills are muslins, tarletans, silks, silk plush, and velvets. Pop., 1901, 12,334; 1911, 12,532.

**TARASCO**, tã-rãs'kõ. An ancient nation of Michoacan, Mexico, constituting a distinct linguistic stock. The early history of the Tarascans is preserved in a very curious Spanish document the translated title of which is "Relation of the Ceremonies and Rites, Population and Government of the Province of Mechuan." According to their traditions they migrated from the north about the same time as the Aztec tribes (see NAHUATLAN STOCK), and about the year 1200 established their Kingdom in Michoacan, maintaining their independence against the Aztec, whom they excelled in many culture characteristics. Their principal buildings, especially in their capital city of Tzintzuntzan, were of cut stone laid in mortar. Many of the ruins are still unexplored. Their calendar was nearly the same as that of the Aztec, and they had also a pictograph system. Their principal god was Curicaberis, the sun. The dead were cremated, and both their funerals and their religious ceremonials were accompanied by human sacrifices. They were famous for their beautiful and durable fabrics of woven feathers as well as of cotton, and were skillful in the working of gold and silver. They surpassed all other native tribes in their defensive armor, which consisted of helmet, cuirass, and limb protectors, all of wood covered with plates of copper or gold. In physique they were considered the tallest and handsomest people of Mexico. They still constitute the bulk of the population of central Michoacan, and number about 200,000, and although they have lost the art of feather weaving, they maintain their reputation for the weaving of beautiful rebosos and belts with figures of birds and animals, and for their lacquer work. The language is vocalic and euphonic. Despite the fact that they offered no resistance to the Spanish invasion of Mexico, their last King, Tangaxoan, was tortured to death by Nuño de Guzmán. In 1810 they were the first to revolt against the Spaniards, and thus, under Hidalgo, began the Mexican War for Independence. Consult K. S. Lumholtz, *Unknown Mexico* (New York, 1902).

**TARASCON**, tá'rã'skõn'. A town in the Department of Bouches-du-Rhône, France, 13 miles southwest of Avignon, on the Rhone River (Map: France, S., J 5). It is connected with Beaucaire on the opposite bank by a suspension bridge. The twelfth-century church of St. Martha, a composite of the Romanesque and Gothic, occupies the site of an old Roman temple. It was rebuilt during the fourteenth and fifteenth centuries. It has a tenth-century crypt and the tombs of St. Martha and Louis II of Provence. Other objects of interest include the old Gothic castle completed in the fifteenth century, now a prison, and the town hall. The leading industries are silk spinning and the manufacture of hats. Pop., 1901, 8885; 1911, 8631. Tarascon is the ancient Tarasco. (See

TARASQUE.) Daudet received here the inspiration for his *Tartarin de Tarascon*.

**TARASP**, tã'rãsp'. A village of Switzerland, in the Lower Engadine, Canton of Grisons, situated on the Inn, at an altitude of 3910 feet, 36 miles from Chur and 28 miles from St. Moritz (Map: Switzerland, E 2). It is a health resort, frequented for its mineral baths. Pop., 1900, 275; 1910, 312.

**TARASQUE**, tã-rãsk'. A monster prominent in the local folklore of Tarascon, France, said to have been subdued by St. Martha in early Christian days. On the fête "La Tarasque" an effigy of the beast is carried in procession about the streets of Tarascon.

**TARAX'ACUM**. See DANDELION.

**TARBELL**, EDMUND C. (1862- ). An American figure and landscape painter. He was born at West Groton, Mass., and studied at the Boston Museum School and with Boulanger and Lefebvre in Paris, but was most influenced by the Impressionists. Upon his return to the United States he settled near Boston and soon attracted favorable attention with his interesting and characteristic New England interiors. His technique is consistently impressionistic, displaying a subtle treatment of color tones, luminous light and shade effects, and clever handling of textures. Among his best-known paintings are: "Josephine and Mercié" (Corcoran Art Gallery, Washington); "Woman in Pink and Green" and "Girl Reading" (Cincinnati Museum); "The Venetian Blind" (Worcester Museum); "The Golden Screen" (Pennsylvania Academy of Fine Arts, Philadelphia); "Girl Reading" and "My Children in the Woods," among others in the Boston Museum; and "Afternoon Tea" (Wilstach collection, Philadelphia). Tarbell became a member of the National Academy (1906), of the "Ten American Painters," and of the National Institute of Arts and Letters, and from 1889 was instructor in drawing and painting in the Boston Museum School. His many prizes include gold medals at the Pennsylvania Academy of Fine Arts, Philadelphia (1895 and 1911), Carnegie Institute, Pittsburgh (1909), and the National Academy of Design (1909).

**TARBELL**, IDA MINERVA (1857- ). An American author, born in Erie Co., Pa. She graduated at Allegheny College in 1880 (A.M., 1883) and from 1883 until 1891 was associate editor of the *Chautauquan*. From 1891 until 1894 she studied at the Sorbonne and at the Collège de France. On her return she became an associate editor of *McClure's Magazine*, and in 1906 assumed a similar position upon the *American Magazine*. Allegheny and Knox colleges honored her with the degree of L.H.D. Her writings, direct, vigorous, and notably informative, include: *Life of Napoleon Bonaparte* (1895; 2d ed., 1901); *Madame Roland: A Biographical Study* (1896); *Early Life of Abraham Lincoln* (1896), with J. McCan Davis; *Life of Abraham Lincoln* (1900); *History of the Standard Oil Company* (2 vols., 1904); *The Tariff in our Times* (1911); *The Business of Being a Woman* (1912); *The Ways of Woman* (1915)—all this in addition to much miscellaneous work for the magazines.

**TARBES**, tãrb. The capital of the Department of Hautes-Pyrénées, France, on the left bank of the Adour, 32 miles by rail east by south of Pau. (Map: France, S., E 5). The cathedral, dating from the twelfth century, with a fine

octagonal lantern tower, is the most noteworthy building. It has manufactures of woollens, machinery, and cannon. The town became a bishopric in 420 and in mediæval times was the capital of the County of Bigorre. It was occupied for 40 years by the English during the fourteenth century. Pop., 1901, 26,055; 1911, 28,615.

**TARBORO**, tãrb'ũr-ũ. A city and the county seat of Edgecombe Co., N. C., 65 miles (direct) east of Raleigh on Tar River, and on the Atlantic Coast Line and the East Carolina railroad (Map: North Carolina, E 2). Cotton, knit goods, cottonseed oil, fertilizers, carriages, foundry and machine-shop products, and lumber are manufactured. Pop., 1900, 2499; 1910, 4129.

**TARDE**, tãrd, GABRIEL (1843-1904). A French sociologist and criminologist, born at Sarlat (Dordogne). In 1880 he began to contribute to the *Revue Philosophique*, and gradually won his way to reputation, which was assured after the publication of his *Lois de l'imitation* in 1890 (Eng. trans., *The Laws of Imitation*, 1903). He later became professor of modern philosophy at the Collège de France in Paris. In a large number of books and articles, Tarde elaborated a complete and original theory of society. It is essentially a psychological theory. In Tarde's view, to study society is to study how the minds of men act, and how they influence one another. The essence of society, he held, is that one man should be so affected by another that the two should be brought to greater similarity of thought or action. Social life is a round of invention and imitation; an "invention" being a new thought or act of any kind, and "imitation" any thought or act of copying or making after a model. Imitation obeys certain laws which Tarde began to investigate. Thus it is usually the inferior who copies the superior, the lower class the upper class—a new idea having prestige because of its novelty, though if taken up as a permanent institution it will come to prestige by lapse of time. Circles of imitation spread from different inventions as ripples around stones thrown on a pond; the circles interfere, oppose, combine, in complicated ways which Tarde sought to analyze. The essentials of his theory were presented in the *Lois de l'imitation*, and were elaborated five years later in his *Logique sociale*, in which extensive illustrations were given from the whole range of social development. Along with his sociological theory, Tarde gradually developed a philosophical system, best summarized in his *Lois sociales* (1898; Eng. trans., *Social Laws*, 1898). His psychological point of view is carried over into his criminological work. *La criminalité comparée* (1886; 5th ed., 1902), his first book, emphasized the purely social influences upon crime, with much criticism of the anthropological school of Lombroso (q.v.). *La philosophie pénale* (1890; Eng. trans., *Penal Philosophy*, 1912) is a more systematic presentation of his ideas. Tarde's other works include: *Etudes pénales et sociales* (1892); *Les transformations du droit* (1893); *Essais et mélanges sociologiques* (1895); *L'Opposition universelle* (1897); *Etudes de psychologie sociale* (1898); *Les transformations du pouvoir* (1899); *L'Opinion et la foule* (1901); *Psychologie économique* (2 vols., 1901). A volume called *Underground Man* appeared in 1905. Consult *Gabriel Tarde: Introduction et pages choisies par ses fils, suivies de poésies inédites*, with preface by Henri Bergson (Paris, 1909).

**TARDIEU**, tãrd'yẽ. A French family of en-

gravers. NICOLAS HENRI (1674–1749), born in Paris, was a pupil of Gérard Audran and later became court engraver. His most important works include a series from the “History of Constantine,” after Rubens, and plates after Rigaud and Watteau. His son and pupil, JACQUES NICOLAS (1716–91), made a specialty of portraits. He succeeded his father as court engraver, and was also appointed engraver to the electoral court of Cologne.—JEAN CHARLES (called Cochin) (1765–1830), a son of the preceding, was a historical painter, and a pupil of Regnault. “The Queen of Prussia at Tilsit” and two other paintings at Versailles are by him.—JEAN BAPTISTE PIERRE (1746–1816), a grand-nephew of Nicolas Henri, was the first to raise the art of geographical engraving to a high level, and was ably followed in its practice by his brother ANTOINE FRANÇOIS (1757–1822), as well as the latter’s son AMBROISE (1788–1841). PIERRE ALEXANDRE, nephew and pupil of Jacques Nicolas, also studied under Wille. He engraved chiefly portraits, including the fine plate of Lord Arundel, after Van Dyke.

**TARDIGRADA**, tîr’dî-grâ’dâ (Lat., slow-going). A group of animals of uncertain affinities, represented by the bear animalcules. They are minute, slowly moving, soft-skinned animals, not more than a millimeter in length, and are often referred to the class Arachnida, as distantly related to the mites. The body is short and thick, not divided into segments, the head slightly separated from the trunk. The mouth is provided with a sucking proboscis, and is surrounded by papillæ. The digestive canal opens by a muscular pharynx into a narrow œsophagus, which leads to a capacious stomach, succeeded by a short intestine. There are two eyelike spots, and the nervous system consists of a brain succeeded by a ventral nerve cord of four ganglia. There are no heart, blood vessels, nor any respiratory organs; and the animals are hermaphroditic. The segmentation of the egg (which is very large) is complete and regular. Tardigrades are not uncommon in bog moss (*Sphagnum*), or in fresh and salt water, and are capable of revivifying after being apparently dead and dried up, if placed in water.

**TARDIGRADA**. A subdivision of Edentata. See SLOTH.

**TAR/DIVEL**, JULES PAUL (1851–1905). A Canadian journalist and novelist. He was born at Covington, Ky., and went to Canada in 1868. He was educated at St. Hyacinthe College, took up newspaper work, and after serving on the staff of *La Minerve* and *Le Canadien* he founded in 1881 *La Vérité* (Quebec), of which he was for many years editor and proprietor. He was independent in politics, strongly pro-Catholic, and strove to make Catholic principles rule in the conduct of public affairs. He was a bitter enemy of liberalism and the Freemasons, and favored the secession of Quebec from Confederation and the eventual independence of the province. He published: *Vie du Pape Pie IX, ses œuvres et ses douleurs* (1878); *Notes de voyage* (1890); *Pour la patrie: roman du vingtième siècle* (1895), in which he attacks the influence of Freemasonry.

**TARE** (of uncertain etymology; possibly connected with ME. *tare*, brisk, eager). Various leguminous plants, especially species of *Vicia*, weak climbing plants, natives of the temperate parts of the Northern Hemisphere. One of these, the wild vetch (*Vicia hirsuta*), has very small

flowers and pods, pinnate leaves, and small leaflets. It affords nourishing food for cattle, but the quantity is so small that it is seldom cultivated and is chiefly known as a weed. One species (*Vicia sativa*), with an upright branching

VETCH.

habit, is cultivated in some parts of Europe for its herbage. The plant thrives well in poor sandy soils, where it is valuable for green manure. *Vicia villosa*, the hairy or winter vetch, is also a valuable forage and green manuring plant. (See VETCH.) The tare of the New Testament is supposed to be darnel (q.v.).

**TAREN'TOLA** (It., Tarentine, from *Taranto*, from Lat. *Tarantum*, from Gk. *Tápas*, *Taras*, a city of southern Italy), or **TARENTE**. One of the commonest geckos (q.v.), or lizards, of the Mediterranean region (*Tarentola mauritanica*), grayish brown with indefinite markings, and about 6 inches long. It has been introduced by ships into southern France, and when it takes up its abode inside a house becomes almost domesticated. Some other geckos are also mistakenly called by this name. An interesting account of their habits may be found in Hans Gadow, “Amphibia and Reptiles,” in *Cambridge Natural History*, vol. viii (London, 1901).

**TAREN'TUM**. See TARANTO.

**TARENTUM**. A borough in Allegheny Co., Pa., 22 miles northeast of Pittsburgh, on the Allegheny River, and on the Pennsylvania Railroad (Map: Pennsylvania, B 6). It is primarily an industrial centre, being interested largely in the manufacture of plate glass and bottles. Other products include brick, lumber, steel and iron novelties, steel billets and sheets, sack and wrapping paper, etc. Pop., 1900, 5472; 1910, 7414.

**TARGE**, FRANÇOIS HENRI RENÉ ALLAIN. See ALLAIN-TARGE, F. H. R.

**TARGET AND TARGET PRACTICE**.

Target practice is the scheme of instruction and training designed to produce effective use of projectile weapons under war conditions. The word “target” is used to designate either the actual or simulated hostile personnel or material. There are, e.g., special systems of target practice for—1. Small arms: including the rifle, the pistol, and the machine gun. 2. Light and heavy field artillery: cannon from 3-inch to 6-inch. 3. Siege artillery: from 6-inch to 16-inch calibre. 4. Coast artillery:

guns, mortars, submarine mines. 5. Miscellaneous projectile weapons: hand and rifle grenades; army and navy balloon guns for use against aircraft; small arms and machine guns fired from aircraft against aircraft; bombs, torpedoes, and steel arrows launched from aircraft at land and water targets, etc. 6. Naval guns and torpedoes fired from a moving ship or submarine against other ships in motion.

The general scheme of any system of target practice includes a preliminary training of the individual and organization in principles and methods, followed by tactical fire problems (with service ammunition), simulating as far as possible the technical and tactical conditions of a definite phase of actual combat. The targets for these final or test exercises simulate in form, color, size, movement, etc., the actual targets to be expected in war.

**Small Arms: Rifle and Pistol.** The sole purpose of rifle training for the soldier is to make of him a good shot under war conditions, and a scheme of instruction will be effective in so far as it tends to produce that result. The soldier is therefore so trained at known distances in the various kinds of fire employed in actual service as to bring his skill as a rifleman up to the capabilities of his weapon, after which he should be so trained in firing as a part of tactical units as to utilize his individual skill to the best advantage in operations simulating those of the battlefield. By means of preliminary drills and gallery practice the soldier is trained in the fundamental principles of marksmanship; by means of range practice he is taught to apply these principles in firing at fixed distances, at clearly defined targets. This training is merely preparatory to combat firing in which individuals learn coöperation, and commanders and leaders learn how to obtain the maximum efficiency of fire by a judicious coördination of the skill and the efforts of all the individuals of the group or fire unit.

United States soldiers using the rifle are graded according to proficiency exhibited in the individual record practice. The test is a single course in slow and in rapid fire as given in the following table:

SLOW FIRE					
RANGE YARDS	Time	Shots	Targets	Value	Position
300	No limit	10	A	50	5 sitting, 5 kneeling
500	No limit	10	B	50	Prone
600	No limit	10	D	50	Prone, sandbag rest
RAPID FIRE					
200	1 min.	10	D	50	Kneeling from standing
300	1 min. 10 sec.	10	D	50	Prone from standing
500	1 min. 30 sec.	10	D	50	Prone
Total possible.....300 points					

The grades of marksmanship, based on the above firing (the number of points being those made out of a possible 300), are as follows: expert rifleman, 253; sharpshooter, 238; marksman, 202; first class man, 177; second class man, 152. The targets A, B, and D used in this record firing are as illustrated in Figs. 1,

2, and 3. The value of a bull's-eye hit is 5 points, the other zones 4, 3, and 2 points respectively counting from the centre. Long-distance practice for sharpshooters and experts

FIG. 1. TARGET A.

FIG. 2. TARGET B.

only is conducted at 800 and 1000 yards firing from the prone position at target C, Fig. 4. Value of zones in points as in A and B targets. The course in pistol firing is both mounted

FIG. 3. UNITED STATES ARMY TARGET D.

and dismounted. The dismounted course is at 15 and 25 yards; for experts, 15, 25, and 50 yards. For the mounted course, at the halt and gallop, firing is at 10 yards. Expert test at

FIG. 4. UNITED STATES ARMY TARGET C.

5 to 15 yards at the halt, gallop, and extended gallop.

Extra compensation in money and a badge are given to enlisted riflemen qualifying for the higher grades. Commissioned officers are given

badges only. For the purpose of fostering interest in target practice, department competitions are held for the regular army in every alternate year, or when directed by the Secretary of War. Gold, silver, and bronze medals are awarded to department teams according to order of merit.

The National Board for the Promotion of Rifle Practice, with the approval of the Secretary of War, issues from time to time rules and regulations for national matches and other competitions. The national matches include

FIG. 5. MOVING TARGET.

rifle teams of 12 men each from the United States infantry, the United States cavalry, United States navy, United States marine corps, United States Military Academy, one team from the organized militia of each State, Territory, and the District of Columbia, one team from the university, college, military school or college whose members can present a certificate showing good scholastic standing and the amount of military duty required. There are also national individual rifle and pistol matches held at the same time and place.

After the individual target practice at known distances at well defined targets the training of the rifleman proceeds to collective firing of 20 to 25 rifles at unknown distances, against field targets which are groups of silhouettes, made of wood or fibre, painted olive drab, and in size and shape simulating enemy personnel and horses, which targets are so disposed over the natural terrain as to represent an actual

among the soldiers of other armies. For further details consult *Small Arms Firing Manual United States Army* (Washington, 1913) and *Field Firing and the Proficiency Test, United States Army* (ib., 1911).

**Machine Gun.** For machine guns which played such an important part in the Great War, special target practice is provided. The squad handling a gun is practiced in directing the gun quickly upon a suddenly appearing target, in following its movements and in keeping up an effective fire against it. Field targets

moving at various angles to the front and at different rates of speed are used. Such targets afford different and unknown ranges and different degrees of visibility. The method of instructions, nature of targets, etc., may be found in the *Combined Infantry and*

*Cavalry Drill Regulations for the Automatic Machine Rifle, Calibre 30, United States Army* (1915).

**Field Artillery Target Practice** is essentially different from that for small arms. The accuracy of fire of the rifleman is obviously dependent upon one man, that of the field gun upon a squad of five or more men and the skill of the officer observing the fire. Normally the rifleman cannot bracket his target by the observation of the points of impact of his bullets, whereas the field artillery officer can observe and uses the bursts of his projectiles for that purpose during the ranging process. The rifleman uses direct fire, i.e., aligns his sights on the object attacked, whereas the artillery gunner, firing normally from behind cover, does not see his target but secures the correct laying of his gun by setting off on scales data computed by the officer observing the fire. The system involves team training at the guns, cal-

FIG. 6. DISAPPEARING TARGET.

episode in war. Companies, battalions, and regiments have similar exercises. Such field targets may be stationary, disappearing, moving, or a combination of two or more. Examples of such field targets are illustrated in Fig. 5 and Fig. 6.

The armies of all the great powers use similar methods and targets. The British and the United States soldier has more individual target practice, especially at the long ranges, than the rifleman of Germany and France, but the German and French infantry have more training in collective firing in tactical problems. As a marksman the American soldier ranks high

in the collection of firing data by the officer and a sure communication system, verbal, telephone, or flag; from the officer's observing station to guns, and correction of range, height of burst and deflection errors, based on the observation of preceding bursts. In addition, in the exceptional cases when field guns use direct fire, the enlisted gunner must have a training in laying his gun similar to that of the rifleman.

The target practice of field artillery in the United States army includes pistol practice, subcalibre practice and service practice. Subcalibre practice is with a dummy cartridge

whose axis is a tube the calibre of which is that of the small arm rifle ammunition, which is used for purposes of economy in training preliminary to service practice, in which service ammunition is used. Service practice problems, the culmination of the years' training, are always conducted as phases or episodes of combat, over the natural terrain, at unknown ranges, at field targets, fixed, disappearing, and moving,

ing the target is based both on observation of bursts and on accurate trigonometrical data (obtained by instruments at the ends of a base line). The targets used simulate those for which the particular calibre was designed.

**Coast Artillery.** This target practice consists of practice with (1) 3, 4, 4.7, 5, and 6 inch guns; (2) 8, 10, 12, and 14 inch guns; (3) 12-inch mortars; (4) submarine mine practice.

All service target practice with guns and mortars, except trial shots, is by battery at moving targets towed as fast as is practicable with the available vessels, the distance of the latter from the targets being 300 to 500 yards. For the record shots of the small guns, 3 to 6 inch, a material target 10 feet high by 24 feet long, mounted on towed rafts, is used. The practice

FIG. 7. ADVANCING INFANTRY TARGET AND SLED.

constructed usually of inch pine lumber simulating in form, size, color, disposition, and movement hostile personnel, animals, and material. Material objects, such as stone walls, earthworks, buildings, etc., when available, are also fired at to exhibit actual effect obtained. For the details of methods consult the annual training and target practice order published by the War Department. All ranges from the gun to about 5000 yards are used. The permanent artillery ranges in England, Germany, and other European countries are in general similar to the one which was being equipped at the School of Fire for Field Artillery at Fort Sill, Okla., in 1915. European equipment includes concrete and armored towers for observers near the targets, permanent protected power plants to move the targets at different speeds by means of long cables, permanent telephone lines to connect observers with firing points, etc. In the United States targets are drawn by six-horse limbers at the end of a 500-yard cable. One of the most realistic targets, adopted from the German, is illustrated in Fig. 7. It consists of a line of infantry skirmishes so arranged that it moves as a whole while appearing and disappearing at irregular intervals, thus representing an advancing infantry squad intermittently seeking cover. Fig. 8 is a gun team and carriage target, mounted on sleds and drawn by a six-horse limber. Consult: Bethell, *Modern Artillery in the Field* (London, 1911); *Index of Targets*, School of Fire (Fort Sill, Okla., 1915); *Mobile Artillery Targets* (Washington, 1914).

**Siege Artillery.** This target practice partakes of the character of both field and sea-coast artillery (see below), i.e., the means of reach-

ing is similar to that for field guns firing at moving targets, corrections being based on observation of splashes and direct hits only counting. For the large guns and mortars any form of towed target is used as an aiming point. The splashes are carefully plotted on a sheet with reference to the target. The centres of silhouettes of the vertical and horizontal projection of a battleship, drawn to scale, are placed on the plotted position of the aiming point and hits are allowed or rejected as they do or do not fall within the outlines of the silhouette. Minimum ranges are from 3000 yards to 10,000 yards, depending on the calibre of the gun. A figure of merit based principally on hits and time used is computed for each company, which is graded accordingly. The practice with the big guns and mortars is essentially different from that of the field artillery gun. For the coast artillery, gun range corrections are based on rapid instrumental plotting, since personal observations of

FIG. 8. ARTILLERY TARGET. GUN TEAM AND CARRIAGE TARGET.

shorts and overs have been found unreliable at the long range used. With the field artillery gun a target is included between two observed salvos and the fire for effect delivered between them.

**Mines.** Besides the gun practice mine companies have submarine mine practice annually, firing loaded mines under the conditions of war service. An improvised target is towed across the mine field at the end of a 300-yard tow line. The movement of the target is plotted instrumentally on a chart showing the

mines, that mine judged to be under the target being fired electrically from the shore. The material target is assumed to be at the centre of a hypothetical circular target 75 feet in diameter. As in field artillery, subcalibre target practice is part of the training preliminary to practice with service ammunition. Consult: *Coast Artillery Instruction Order, U. S. A., 1916*; *Drill Regulations Coast Artillery, 1914*; Hines and Ward, *The Service of Coast Artillery* (New York, 1910).

**Miscellaneous Projectile Weapons.** To secure both efficiency and economy of material, practice with grenades thrown by hand is necessary. Practice with the various forms of rifle grenades, some of which have a range as great as 300 yards, is as necessary as target practice with trench mortars. The great value of such projectile arms was exemplified during the Great War.

Balloon gun is the name popularly given to the ground gun designed to attack aircraft. Their development and use during the Great War was notable. Target practice with such guns is against kites and balloons, both free and captive. The development of this armament is so recent that in 1916 there were no prescribed manuals for public information. The problem of vertical fire against aircraft moving in three dimensions is difficult and is not yet satisfactorily solved. Aircraft guns are the armament of aircraft whose targets are other aircraft. Target practice with such guns is in an embryonic stage owing to the fact that it is only within the last few years that such guns have been used. But it may be said that the hitting of one moving body from another moving body, both going at a high rate of speed, presents a difficult problem in exterior ballistics of three dimensions. Similarly, launching apparatus for dropping bombs and other projectiles from aircraft is in an experimental stage and up to 1916 little military success had been achieved. Lieutenant Scott, formerly of the United States army, devised such an apparatus, which met with considerable success in French experiments conducted before the Great War. Targets used for such practice include concentric circles of known diameter, or the outlines of a ship's deck, marked on the ground, silhouettes representing bodies of troops, etc. Two elements must be known, first, the ground speed, i.e., the speed at which the aircraft is passing over the ground (the resultant of the aircraft's speed, and the retarding or accelerating effect of the wind), and second, the height above the ground. For data on aeroplane observers in the conduct of the fire of artillery, consult *Extracts from Field Artillery Training* (British), 1914, relating to *Aircraft* (Fort Sill, Okla., 1915). See MILITARY AERONAUTICS; NAVAL AERONAUTICS; TARGET PRACTICE, NAVAL; TORPEDO.

**Civilian Rifle Practice.** There was no organized effort to develop skill in rifle shooting in the United States before 1867, when Capt. George W. Wingate (q.v.), in command of Company A of the Twenty-second Regiment, New York National Guard, formulated instructions on the subject for that company. The elaboration of these instructions and their publication in the *Army and Navy Journal* led to the formation at New York, in 1871, of the National Rifle Association of America, which has ever since been the most active agency in encouraging both

military and civilian rifle practice in the United States. Largely through the efforts of this association New York State, New York City, and Brooklyn gave \$25,000 in 1872 for the establishing of the famous rifle range at Creedmore, Long Island, which was used for military matches continuously thereafter until 1909. Here was held in 1874 the first international rifle match in the United States, the contestants being a team of five men from the Amateur Rifle Club, representing the National Rifle Association, and a team of the same number of Irish rifle experts, representing the British National Rifle Association. This remarkable contest was won by the American team by a score of 934 to 931. American teams were also successful in Ireland in 1875; against Irish, Scottish, Australian, and Canadian teams at Creedmore in 1876; and once more in Ireland in 1880. The development of purely military rifle matches on the Creedmore and other ranges is discussed in the preceding part of this article.

Governmental efforts to encourage civilian rifle practice may be said to date from the formation, under an Act of Congress approved March 2, 1903, of the National Board for the Promotion of Rifle Practice. The board (which is affiliated with the War Department) is composed of the president and the seven directors of the National Rifle Association, eight members selected by the Secretary of War from the country at large, and five selected as representatives of the War Department, the army, the navy, and the Marine Corps. The board has no administrative force, and its work is carried on by the National Rifle Association, whose headquarters are in Washington. Further official support was expressed in 1912 when the Secretary of War asked all governors of States to request National Guard officers in their jurisdiction to put the State rifle ranges at the disposal of college and school-boy rifle clubs and to assign militia officers as instructors for such organizations. Nearly all of the governors replied favorably to this request. Again, in 1914 Congress sanctioned the issue of a Krag-Jørgensen rifle and 120 rounds of ammunition to each member of a civilian rifle club affiliated with the National Rifle Association. In 1915 the Secretary of War approved the plan of that association for an annual competition between teams from civilian rifle clubs recognized by the association for the championship of the United States, these contests to be held simultaneously on military ranges, under military regulations, and with the regular service rifle.

Great impetus had been given to the movement in 1907 by the action of the National Rifle Association in amending its by-laws so as to admit to membership rifle clubs representing colleges which grant degrees, academies, preparatory schools, and public schools, the minimum membership age to be 14 years. The New York City Public School Athletic League (organized in 1903) had already introduced rifle practice for high-school boys by means of a "subtarget gun" machine, employing the service rifle without ammunition, but equipped with an electrical device which registers accurately the shooter's aim.

Under these various influences there was a rapid increase in the amount of civilian rifle practice throughout the United States during the decade 1905-15. According to the report of the secretary of the National Rifle Association

covering the year 1915, there were affiliated with the association at the beginning of 1916, 639 civilian rifle clubs with 26,212 members, 64 college and university clubs with 3353 members, 87 high-school clubs with 2788 members, 10 private preparatory school clubs with 867 members, 32 military school clubs with 2106 members, and 9 boys' clubs with 139 members, making the total membership of these clubs 35,465. Similar interest was shown in this subject in Europe, and received due attention in the pamphlet, *Rifle Shooting in Educational Institutions* (2d ed., 1912), published by the National Board above mentioned. Consult "Shooting News," published monthly by that board, and its annual reports; also the annual reports of the National Rifle Association.

**Trap Shooting.** The obvious brutality of shooting pigeons released from a box within comparatively easy range of the shooter has caused the prohibition of that practice in all but a few of the United States and the substitution for the live birds of inanimate targets thrown from various forms of spring traps. Glass or tar-composition balls were the first of these targets to gain any vogue, but these were soon displaced by the clay pigeon, which was first made by George Ligowsky of Cincinnati, Ohio. Ligowsky used common clay, which he modeled into the form of a deep-bowled saucer and baked in an ordinary oven; but the cost of this target (about \$30 a thousand) was almost prohibitive, while the crude method of manufacture caused great variation in its hardness, many, indeed, being practically unbreakable by ordinary bird shot. In 1882 the American clay bird, made of a composition of pitch and tar, was produced, but proved to be too fragile and prompted the invention by two brothers named Hebbard, of Memphis, Tenn., of a target composed in equal portions of pitch and finely ground, kiln-dried river clay. These targets are cast in various molds, but are generally  $4\frac{1}{8}$  inches in diameter and  $1\frac{1}{8}$  inches high, with a rim  $\frac{1}{4}$  inch thick and  $\frac{1}{2}$  inch high, the body being raised  $\frac{5}{8}$  of an inch from the inside of the rim. The Hebbard target was named the Blue Rock and has remained the standard form. Such targets sell for from \$5.50 to \$6 a thousand. They are thrown from a trap with an arm propelled by a powerful spring, which gives the target a rotary motion and a steady and rapid flight.

It was estimated that there were about 500,000 trap shooters in the United States in 1916 and about 5000 gun clubs devoted chiefly to this sport. In that year these shooters were using targets at the rate of from 60,000,000 to 70,000,000 a year, while foreign clubs use about 10,000,000 annually. The various State gun clubs hold a State shoot every year, and the winners of these contests compete for the amateur championship of the world, which is held under the direction of the Interstate Association. In 1915 this contest engaged 853 shooters. Various other handicaps and straight shoots are also held under the management of the Interstate Association.

**TARGET PRACTICE, NAVAL.** Target practice is the culminating exercise in the preparation of ships and crews for war. The methods and details are constantly changing and to a certain extent both are confidential. After the men are thoroughly trained at the guns they are given practice with dotters and subcalibre

tubes or similar apparatus. These are devices (attached to the guns) which fire at miniature moving targets or make pencil records on moving sheets. By this means the poorer marksmen are eliminated. The training is then advanced to subcalibre practice. One-pounder or other guns of small size are securely clamped to the chase (i.e., the forward barrel) of the heavy guns. The operator uses the sights and elevating mechanism of the big gun but fires a projectile from the small one, a suitable correction being made for the difference in range of the two pieces with a given elevation. The best marksmen are selected as gun pointers and record practice is then held. Large canvas targets are stretched on masts erected on a long wooden raft. This raft is towed at the end of a long hawser and the targets are fired at by the guns of the firing ship. The range is several thousand yards, the exact distance depending upon the calibre and characteristics of the guns used, and is frequently changed. As the secondary battery of ships is used for torpedo protection, its practice takes place at night, searchlights being used to illuminate the target. Several guns may fire at one target at the same time, but the hits are distinguished by freshly coating the points of the shells with different colored paints before firing and the color of the paint shows around the hole made in the target. Upon the results of record practice are based the rewards to the individual gun pointer, gun captain, guns' crews, ships' crews, etc., though they may be increased by battle practice records.

Battle target practice is intended to simulate war conditions. The exact regulations are different in each navy and are apt to change from year to year. The targets are towed at an unknown speed and on an unknown course. The firing squadron or division is given no information beyond what its commander or individual ships can ascertain while approaching it from a distance beyond the permitted range for firing. The manoeuvres of the fleet while firing, the limits of range and time in which firing is permitted, and the number of shots to be fired are of course specified. Several targets are usually towed in the target group—one for each ship, one for each pair of ships, one for each division, as may be specified.

Night battle practices are rarely the same in any two navies or in the same navy in any two consecutive years. All are intended to simulate the conditions of night attack by torpedo boats. In addition to the regular target practices, special practices are undertaken by selected ships. These are devised to solve problems in gunnery, armor, tactics, or to obtain improved methods of target practice. The necessary expenditure for target practice is very great but, as it is the most valuable and necessary of all training for war, the expenditure is accepted as inevitable. All practicable means for reducing the cost are taken—such as the use of cheap cast-iron projectiles filled with sand and wood instead of a bursting charge, thereby effecting a saving in each discharge of nearly fifty per cent, as the steel projectile and bursting charge make up nearly two-thirds the cost of every shot. See GUNNERY; GUNS, NAVAL.

**TARGOVITZA**, tăr'gô-vî't'sá, CONFEDERATION OF. A union of Polish nobles under the leadership of Felix Potocki, formed at Targovitza

(Russian Government of Kiev) on May 14, 1792, for the purpose of overthrowing the constitution adopted in the preceding year. The organizers of the confederation were entirely in the interests of the Russian Empire, and the adhesion of the Polish King to the confederation was followed by the second partition of Poland (q.v.).

**TARGUM**, *tār'gūm*; *Heb. pron. tār-gūōm'* (Aram. *targūm*, translation, explanation, from *targūm*, to interpret). The designation of the Aramaic paraphrases of the Old Testament used in the synagogues of Palestine and Babylonia. When Hebrew ceased to be generally spoken and gave way to the Aramaic, it became necessary to explain the meaning of what was read from the Scriptures. The first indication of this practice is to be found in Neh. viii. 8, where it is said that Ezra read the law to the people while his assistants "caused them to understand the reading." The custom grew and gradually there arose a class of *meturgemans* (mod. *dragoman*, interpreter) and finally the system was regulated by the rabbis. At first and indeed for many centuries the Targum from its very nature was not committed to writing, for the same reason that the oral law itself was never intended to become a definitely formulated written code. In the course of time, however, both yielded to circumstances and it was thought preferable to write them down rather than have them forgotten. Yet only a small portion of the immense mass of oral Targums that was produced survived. We possess the originally Judean Targum Onkelos and three late and incomplete so-called Jerusalem Targums on the Pentateuch, the Judean Targum ascribed to Jonathan ben Uzziel on the Prophets, as well as later fragments of another paraphrase of the Prophets, and Targums on the Hagiographa, viz. on Psalms, Job, Proverbs, the five Megilloth (Song of Songs, Ruth, Lamentations, Esther, Ecclesiastes), on Chronicles, and on the deuterocanonical pieces of Esther. There are no Targums on Daniel and Ezra and Nehemiah.

The Targums are seldom of much help for purposes of text criticism. Their main claim upon scholars rests upon the fact that in them there are to be found hints at the internal and external life of the people at the time when they were composed, and that they disclose the development of religious thought and of Scriptural interpretation from the first to the seventh century of our era. The text is in a very corrupt condition, as might indeed be expected, since no proper care was taken to secure the purity of the text when the Aramaic began to decline as the spoken tongue of the Jews. A translation of the Targums on the Pentateuch into English was made by Etheridge (London, 1862-65). The *Editio Princeps* of Onkelos (q.v.) is that of Bologna (1482), of the Targum on the Former Prophets that of Leira (1494), and on the Latter Prophets that of Venice (1517-18). Targums on the Hagiographa appeared in the Rabbinic Bibles, but the Targum on Chronicles was not published until 1680. Recent editions of the Targum are: Pentateuch (Targum Onkelos) by A. Berliner (Berlin, 1884); Prophets (Prophetæ Chaldaice) by Lagarde (Leipzig, 1872); Hagiographa Chaldaice by the same (ib., 1873); the Yemenite Targum of Onkelos was published in Jerusalem (1894-1901). Consult especially

Gustaf Dalman, *Grammatik des jüdischpalästinischen Aramäisch* (2d ed., Leipzig, 1905).

**TARGUVISHTEA**. See TERGOVISTE.

**TARIFA**, *tā-rē'fā*. A seaport town of Spain, in the Province of Cadiz, on the coast, 21 miles west-southwest of Gibraltar (Map: Spain, C 4). It is the most southern town of Europe, is surrounded by tower-embattled walls, and communicates by a causeway with a small island, on which stand a fortress and lighthouse. The town is the most thoroughly Moorish in Andalusia; it is quadrangular in shape, and its streets are narrow and dark. Tunny and anchovy fisheries are actively carried on. Tarifa, the Carthaginian Josa, and the Roman Julia Traducta, received its present name from the Arabs, who are said to have called it after Tarif ibn Malik, who landed there to reconnoitre previous to the conquest of the country. It was successfully defended in 1812 by 2500 troops (mostly British) against a French force of 10,000 men, under Victor and Laval. Pop., 1900, 11,730; 1910, 12,522.

**TARIFF** (OF., Fr. *tariffe*, Fr. *tarif*, from Sp. *tarifa*, price list, rate book, from Ar. *ta'rifa*, *ta'rif*, notification, inventory, from *arafa*, to know). A schedule of duties or imposts levied upon goods as they pass from one state to another. A tariff may be levied upon foreign goods: (1) simply as a means of augmenting the revenues of a government, in which case it is a form of taxation (see TAX; FREE TRADE); or (2) as a means of retaliating upon foreign governments for similar restrictions imposed by them, in which case it becomes an instrument of warfare serving a temporary purpose and designed in the end to secure commercial reciprocity; or (3) as a means of fostering artificially particular industries by protecting them wholly or in part against foreign competition. See PROTECTION.

**History.** Tariffs for revenue seem to have been usual among the civilized nations of antiquity. Among the Greeks, especially the Athenians, a tariff was regularly resorted to for revenue. This was laid upon both exports and imports, and an additional tax collected from vessels engaged in foreign traffic using harbors for anchorage. The regular export and import duty at Athens was 2 per cent, though in time of war, when the state was in pressing need of large sums, it was considerably augmented.

Import and export duties were regularly levied by the Roman state for revenue. The name for this tax used by the Latin writers is *portorium*, a name applied likewise to transit duties and bridge tolls. In the provinces and in newly conquered countries, duties were collected by Roman officials known as *portitores* and *publicani*, and the sums transmitted to the Roman treasury. In some cases, however, the central government, as a favor, allowed the subject state to make its own customs laws, stipulating only that Roman citizens should be exempted from paying any duties imposed. In 60 B.C. all *portoria* were abolished by the Lex Cæcilia so far as concerned the ports of Italy; but Julius Cæsar soon after restored them. Augustus Cæsar still further increased the number of dutiable commodities, and a long list of those which under the later emperors were subject to the payment of a duty is given in the Digest of Justinian. The rate of duty at Rome seems generally to have been 5 per

cent, but under the later emperors a duty of 12½ per cent (octava) is mentioned as the ordinary tax on imports.

In the Middle Ages the feudal lords individually claimed and exercised the right of imposing transit duties levied on all goods that passed by or through their possessions. Hence river ways and roads had many customhouses and tollgates. When feudalism gave away to monarchy and strong central government, the kings took the barons' rights. They erected customhouses at all their frontiers, and even on the boundaries of their different provinces. So universal did duties, local and national, become, that every continental nation was covered with a network of customs lines. Various cities also had their local customs duties, of which the octroi collected at the entrance to several cities on the Continent, notably Paris, is a survival.

In England we first hear of a tariff for revenue under King Ethelred about the year 980. At that time duties on ships and goods were levied and ordered to be paid at Billingsgate, London. They were first acknowledged as a part of the King's revenue in the reign of Edward I, who received them by regular grant from Parliament, if we may accept the assertion of Sir Edward Coke, quoted by Blackstone. But wool, skins, and leather were taxable at the royal pleasure, these being the hereditary customs of the crown, known in the law-Latin as *custuma antiqua*. Subsequently, under Edward, special duties to be paid by foreign merchants only were levied (*custuma nova*), which were protective in their nature and not merely for revenue. The duty on ordinary goods in this reign was sixpence in the pound; raised to one shilling (5 per cent) under Richard II, reduced to sixpence and again raised to eightpence, it was finally fixed at the shilling rate, where it remained till the reign of William III (1697). The King also had the right of prisage, i.e., of taking from every wine-importing vessel of twenty tuns two tuns for royal use. This duty was called tunnage to distinguish it from the other duties called poundage. Customs duties were originally granted for the defense of the realm, and especially for the protection of traffic on the high seas, and were at first given for a fixed period. To Henry VI, Edward IV, and their successors, they were given for life, until the reign of Charles I, whose unconstitutional levy of these duties without grant of Parliament formed one of the grievances against him. On the restoration of Charles II the duties were again granted for life, and under William and Mary they were made perpetual and assigned to the payment of the national debt.

From an early period it was the custom in England to base tariff duties upon official valuations of imports and exports. A book of rates containing such valuations is known to have been printed in 1545. The struggle between the first Stuarts and Parliament over questions of taxation was precipitated by the arbitrary action of James I in raising the official rates without the consent of Parliament. In 1642 the latter body itself issued a book of rates without the assent of the sovereign. After the Restoration a new book of rates was issued in 1668 with the assent of both authorities. This enumerated as many as 212 articles for taxation outward (i.e., export duties) and 1139 articles for import duties. Official valuations continued

to be the basis for tariff purposes all through the eighteenth century, and this is one circumstance which makes it difficult to estimate correctly the value of England's exports and imports during that period. Another confusing practice which prevailed until about 1787 was that of assigning the proceeds from the duties on imports and exports to a variety of different purposes or funds. As a consequence it was often difficult even for customs officials to determine what was the aggregate rate to which a particular article was subject. Pitt's Customs Consolidation Act of 1787 did away with the separate funds by assigning all revenue from duties to the consolidated fund. In this Act some 1200 articles were rated for import duties and 50 for export duties. Another important achievement of Pitt's ministry was the negotiation of a commercial treaty with France (1786) which went far towards freeing trade between the two countries from hampering restrictions. The struggle against Napoleon caused the abrogation of this treaty, but it was the first definite step in the direction of that free-trade policy which England was to adopt some 60 years later. The next simplifications of the English tariff were those effected by Huskisson in 1824 and 1825, which consolidated some 450 trade and tariff acts into eleven and reduced the rates of duty on many articles, particularly exports. One of the most important results of the long struggle for the abolition of the Corn Laws (q.v.) was to simplify still further the English tariff. From 1842 to 1846, 390 duties, including all those on exports, were abolished and 503 were reduced; in 1846, 54 were abolished and 112 reduced; in 1853, 123 were abolished, and finally, in 1860, 371 more were abolished and virtual free trade was achieved. An important incident of the latter year was the negotiation with France of a new commercial treaty which lowered the duty on wine and placed such important French products as silks, gloves, etc., on the free list. For both countries the treaty marked a long step in the direction of free trade, but in the case of France the policy appears to have lacked the support of public opinion and was followed after the Franco-Prussian War by a reaction towards protection. The reduction and abolition of duties continued in England after 1860, the next important change being the placing of sugar on the free list at a sacrifice of some £6,000,000 revenue in 1872. On the outbreak of the Boer War the English tariff included only nine principal items, cocoa, coffee, chicory, dried fruit, tea, tobacco, wine, beer, and spirits. The extraordinary revenue required in connection with that struggle led to the restoration of the duty on sugar, to the imposition of an export duty on coal, and finally to the restoration of light registration duties on grain and flour (3d. and 5d. per cwt. respectively). These duties were repealed after the close of the war.

In the tariff history of France the two commercial treaties with Great Britain that have been referred to stand out as prominent features. Down to the time of the first (1786) the tariff policy of the country had been dictated by extreme mercantilist views of trade. The importation of many commodities was prohibited altogether, while others were admitted only on payment of high duties. Nor was the tariff confined to foreign trade. Each petty

province of France had its system of duties, with the result that it was not unusual for the prices of even such common articles as the grains and salt to differ by 100 per cent or more on the same day in different parts of the country. It required nothing less than the Revolution (Decree of 1790) to free the land from these restrictions on internal trade. The bitter national hostilities which grew out of the Revolution and the brilliant years of Napoleon's ascendancy effectually stifled the aspirations for freer trade which ushered in the period. From 1815 until the negotiation of the second commercial treaty with Great Britain in 1860, the tariff policy of France was highly protectionist. The latter treaty was one of the fruits of the Anglomaniac of Napoleon III and was followed by treaties drafted on equally liberal lines with the more important continental states of Europe, including the German Zollverein (1865). These reduced the rates of duty on French imports to from 10 to 15 per cent *ad valorem*. The same liberal policy was continued substantially until 1881, when an Act was passed substituting specific for *ad valorem* duties and incidentally increasing somewhat the rates. Protectionist sentiment increased after 1881 and by 1892, when many of the commercial treaties negotiated at an earlier period expired, the country was ready for an out-and-out protectionist tariff, including not only high duties on agricultural products and manufactures, but also moderate bounties to producers of silk, flax, and hemp. At this time also the policy of providing maximum and minimum duties (see RECIPROCITY) was introduced. Since 1892 there has been no perceptible abatement in the demand for protection in France, and while French duties are moderate in comparison with those of the United States, she must be included among protectionist countries.

The tariff policy of the states now forming the German Empire first assumed definite form in the German Zollverein (q.v.). The importance of this early federation for tariff purposes in preparing the way for the German Empire is generally conceded. From the point of view of tariff history it is interesting because it enabled Prussia, which was inclined towards free trade during this period, to dominate the tariff policies of her smaller neighbors. A treaty negotiated with Austria in 1853 reduced the duties on trade between that country and the Zollverein, and the even more liberal treaty with France, already referred to, secured the same result for trade with that country in 1865. On the eve of the Franco-Prussian War the tariff of the Zollverein was practically a tariff for revenue only. After the war a reaction towards protection set in. This is clearly indicated in the tariff adopted in 1879, by which the duties on both agricultural and manufactured articles were increased. The policy continued to be only moderately protective until 1902, when an Act was passed which made very substantial concessions to the advocates of protection to agricultural interests. Among the most notable changes were an increase in the duties on grains (the duty on wheat was raised from 32 cents per cwt. to 90 cents) and on draft animals (the duty on horses valued at \$250 or less was raised from \$2.50 to \$22.50).

The changes in the tariff policies of France and Germany that have been described have been paralleled pretty closely in the other countries

of continental Europe. England's example and other influences caused a movement in favor of free trade to extend all over Europe in the decade from 1860 to 1870. This was followed by a reaction towards protection in the more important countries, which has gained in volume until in Germany and Russia, at least, the movement is comparable with the protectionist movement in the United States.

Outside of Europe England's free-trade example has been followed only by two or three of her own dependencies (e.g., India). Protective tariffs are found in Canada, in the Australian colonies, and in Cape Colony, and are well-nigh universal among the independent sovereignties. No country has, however, gone further in this direction than the United States.

**History of Tariff Legislation in the United States.** The earliest tariff in the history of the United States was that approved July 4, 1789. It is interesting to note that the preamble of the Act establishing it states that one of its objects is the encouragement and protection of manufactures, at this early period laying down a principle afterward adopted as the tenet of a political party. In 1817, at the beginning of President Monroe's administration, Congress abolished the internal taxes that had been made necessary by the cost of the War of 1812, and in his message the President recommended the imposition of a protective tariff pure and simple. A temporary protective duty had in 1816 been laid upon cottons and woolsens, and in 1818 this was continued for a period of eight years. The rise of the party of Loose Construction, headed by Henry Clay, was favorable to the principle of protection, as the Strict Constructionists held that Congress could impose a tariff only for revenue. In 1819 a protective tariff bill passed the Lower House, but was rejected by the Senate. The election as Speaker, in 1820, of John W. Taylor, of New York, a declared high-tariff man, gave great encouragement to the Eastern manufacturers, and indicates the increasing influence of the protectionists, although in 1822 the Strict Constructionists were able again to defeat bills embodying the protective principle. In 1824, however, the friends of that principle secured a working majority in Congress, and after a prolonged debate adopted a bill whose essential principle was the exclusion from the American market of such foreign goods as competed with those manufactured in the United States.

In 1827 a convention held at Harrisburg, Pa. (July 30), discussed at length the principle of protection. Only four of the slave States sent delegates. The result of the convention was a petition to Congress praying for an increase of duties on certain articles then manufactured in the United States, a request which the Secretary of the Treasury made prominent in his report of the following December. By this time a strong party had been founded to support the protective system, or the American system, as it was popularly called. The famous Tariff of 1828, adopted by Congress after a debate of six weeks, was the immediate result of this party's propaganda. This went further than any act had previously done in the direction of prohibitive duties. The chief articles on which protective duties were laid were woolen and cotton fabrics. At that time the value of the cotton goods annually imported from Great Britain was fully \$8,000,000, and that of

woolen goods about the same. The exports to Great Britain, on the other hand, of rice, raw cotton, and tobacco (the chief products of the South), reached the sum of \$24,000,000 per annum. The Southern producers naturally feared that if the United States should by a high tariff practically prohibit the importation of a large proportion of British goods, retaliatory measures might lead to a diminution of the Southern exports to Great Britain. It was dissatisfaction with the tariff that led to the famous nullification movement in the South in 1832, in which year Congress, while modifying the Act of 1828, distinctly recognized and retained the protective principle.

On March 3, 1833, the so-called Compromise Tariff, introduced by Henry Clay, was passed. It provided for the gradual reduction of the existing tariff until 1842, after which year the duties on all goods were to be 20 per cent. This measure for the time allayed the excitement in the South; but by the year 1842 it was seen that the financial consequences of the steady reduction of the tariff were extremely serious, since government revenues had decreased to an amount less than the expenses. A new tariff was manifestly necessary. Congress passed a bill continuing the duties imposed by the tariff of 1833, and provided for the division of any surplus revenue among the States. This was vetoed by President Tyler as being a violation of the compromise reached in 1833. A revenue tariff was also vetoed, because it contained the distribution clause, but on its being again passed, without this clause, the President signed it (Aug. 9, 1842). In 1846 a revenue tariff that eliminated altogether the principle of protection was passed, its aim being merely to provide an adequate revenue for government expenses. A still further reduction of duties was made by the tariff of 1857, which fixed them at the lowest figures shown since 1816.

In 1861 the Republican party passed the Morrill Tariff, intended primarily to protect American manufactures. Twice in the same year (August 5 and December 24) the duties were still further increased, less for protection, however, than in order to meet the expenses entailed by the Civil War.

It was not until 1880 that the tariff again became an important issue. The Republicans in nominating General Garfield embodied in their platform a strong declaration in favor of maintaining a scale of duties that should continue to protect American industries against foreign competition. The Democrats began to urge the expediency of modifying a tariff which had been framed to meet the conditions of a time of war, and which, they claimed, was hampering commerce, excluding the United States from the markets of the world, and fostering monopolies. They therefore declared for "a tariff for revenue only," which was afterward explained as a tariff that should give incidental protection. In 1882 provision was made by Congress for the appointment of a commission to report upon the expediency of a reduction of the tariff. This reduction became a question of pressing importance, since revenues had so increased over expenses as to accumulate a large and increasing surplus. The Tariff Commission made its report, and in accordance with its recommendations the Act of 1882, a distinctly protectionist measure, was passed. In 1884, the House being Democratic, the bill known as the

Morrison Horizontal Reduction Bill for lowering the tariff was defeated. The campaign of that year turned to some extent upon the tariff question, for the Democratic platform, while evading the question of protection, demanded a real reduction of tariff duties, as well as legislation to check the aggression of great corporations. The election of Mr. Cleveland appeared to show that the cry of free trade had ceased to alarm the voters, and that they were willing to hear argument upon the questions at issue. The new President's first message (Dec. 16, 1885) recommended a reduction of the tariff, and his message in December, 1887, was devoted exclusively to this topic. In it he stated that the surplus in the treasury was nearly \$140,000,000, demanded as a remedy the immediate abolition of the duties upon wool and other raw materials, and characterized the existing tariff laws as vicious, inequitable, and illogical. In accordance with the views of this message a new tariff measure, the Mills Bill, removing the duty on wool, and aiming at an estimated annual reduction of revenue of fully \$50,000,000, passed the House. The Republican Senate offered a substitute repealing the tax upon tobacco and reducing the duty on sugar one-half, thus securing an estimated reduction of \$65,000,000 per annum. Neither bill became a law.

The defeat of the Democrats in the presidential election of 1888 was possibly due to the prominence of the tariff question, but as the majority of the popular vote was on their side, it was seen that a reform or, at any rate, a revision of the tariff was sooner or later inevitable. Therefore, the Fifty-second Congress took up the matter in earnest, with the result that the famous McKinley Bill passed both Houses of Congress and was signed by President Harrison (September, 1890). By its provisions the annual reduction of revenue was estimated to be some \$66,000,000, of which \$6,000,000 was due to a reduction of internal revenue taxes, chiefly on tobacco. A bounty was provided to compensate producers of raw sugar for the abolition of the duty on that commodity.

One very important feature of the McKinley Act was the section added through the influence of James G. Blaine, then Secretary of State, and known as the reciprocity section. This provided that whenever the President shall be satisfied that the government of any country producing and exporting sugars, molasses, coffee, tea, and hides, or any such articles, imposes duties upon products of the United States which in view of the free introduction of such sugar, molasses, etc., into the United States, he may deem to be reciprocally unequal and unreasonable, he shall have the power to suspend by proclamation the free introduction into the United States of such sugars, etc., from the country in question. See CUSTOMS DUTIES; RECIPROCITY.

On the return of the Democratic party to power in 1893, an effort was made to carry out its promise of tariff reform. A bill framed by William L. Wilson passed the House, and after much amendment by the Senate became a law without the President's signature, Aug. 27, 1894. It made a considerable reduction in many duties, admitted wool free, and provided for an income tax. It was still in the main, however, a protective measure. As a revenue law this act was a failure, partly because the Supreme Court declared the income tax feature

unconstitutional and partly because of the business depression which began in the summer of 1893 and caused a marked falling off in imports. The dominant issue in the next presidential campaign (1896) was the silver rather than the tariff question, but the election of the author of the McKinley Act was naturally construed as a popular verdict in favor of the policy with which his name was identified. A special session of Congress was called in March, 1897, and after prolonged debate the Dingley Act, copied closely in its leading provisions after the McKinley Act, became a law. Duties on wool, woollen goods, cutlery, pottery, and a few other articles were made even higher in this Act than in the Act of 1890. Lumber was still dutiable and hides were taxed out of deference to the "Silver Republicans."

In 1898 (June 13) the so-called "War Revenue Law" was passed to supply the revenue required in consequence of the war with Spain. An interesting feature of this law was that it relied upon increased internal revenue duties, and a purely revenue duty of 10 cents a pound, on imported tea rather than on changes in the general tariff to secure the additional revenue required. During the session of 1902 to 1903 earnest efforts were made in Congress by members of the Republican party representing some of the States of the Middle West (e.g., Wisconsin) to effect a revision of those clauses of the Dingley Act supposed to be favorable to the trusts, but without success. The sentiment for tariff reduction became sufficiently powerful in the following year to force a pledge of tariff revision upon the Republican party in the campaign of 1908. In the struggle for revision, ending with the enactment of the Payne-Aldrich Act of 1909, the conservatives succeeded in preventing any serious reduction in schedules. This repudiation of party pledges gave strong impetus to the insurgent movement within the Republican party, and later to the formation of the Progressive party.

In 1913, with the Democrats in control of all branches of the government, a sweeping revision was put through under the name of the Underwood Act. The most important changes were in the iron and steel schedules, where the raw material and half manufactures were placed on the free list and the finished product suffered a corresponding reduction; free wool; gradual reduction of duty on sugar, with ultimate free sugar in 1916. The duty on sugar, reduced to  $1\frac{1}{4}$  cents a pound, was retained in the revenue law of 1916.

After the Harding administration came into office in March, 1921, it set to work immediately on the tariff question. On May 27, President Harding signed an emergency measure to last six months. On Nov. 16, 1921, it was extended until Congress could pass a permanent measure. High duties were imposed on a large number of farm products, the Secretary of the Treasury was authorized to investigate "dumping," and the dye industry was protected by a provision of non-importation if the dye could be produced in this country. All the time this tariff was in force the House and Senate were working on a new measure, the general duties of which seemed to be above those of the Payne-Aldrich bill. A serious revolt occurred in the Senate when several Republican Senators refused to support the rates of the Finance Committee, because they were too high.

**Administrative Aspects.** There is a marked difference in form between purely revenue tariffs, such as that of Great Britain, and protective tariffs like those of the United States and Germany. In the former only the few articles subject to duty are enumerated and unenumerated articles are admitted free. In the latter all articles that may claim free admission are expressly enumerated in the so-called "free list," and other articles are subject to duty either under the special schedules or under the so-called "drag-net clause," which imposes a certain rate of duty on unenumerated articles. The German tariff of 1902 enumerated nearly 1000 different classes of commodities, while in the American tariff of 1897 the free list alone contains nearly 250 separate items.

Another difference that has frequently characterized protective and revenue tariffs in the United States is that the duties in the former are mainly specific, i.e., based on the quantities or the number of units of the commodities imported, while in the latter they are mainly ad valorem, i.e., a certain per cent of the value of the commodities imported. The preference of protectionists for specific duties is to be explained partly by the greater certainty of such duties, since they cannot be evaded by undervaluations, and partly by their conviction that since protection rather than revenue is the object sought, the ordinary canons of taxation, which prescribe that taxes shall be in proportion to the value of the property taxed, may be disregarded. The identification of specific duties with protection appears to be confined to the United States, since even in free-trade England all the duties now imposed are specific. The administrative advantage of such duties, which are practically self-assessing, need scarcely be dwelt upon.

**TARIFF LAWS.** See TARIFF.

**TARIFFS, RAILWAY.** See RAILWAYS.

**TARIJA**, tá-rě'há. A department of south Bolivia (Map: Bolivia, E 8). Its boundaries are ill defined. Area (est.), 33,000 square miles. The surface in the western part (one-third of the area) is very mountainous, and in the east is flat, resembling the Chaco of Para-

guay, of which it is a continuation. There are extensive forests and large stretches of grazing land. The chief river is the Pilcomayo. The principal industries are agriculture and stock raising, both undeveloped. Extensive mineral resources, especially silver, are unworked. The population is sparse and mostly in the mountainous region. The completion of the La Quiaca-Uyuni railway will afford the department a better outlet and produce a rapid development of the region. Pop., 1900, 102,887; 1914 (est.), 146,099. Capital, Tarija (q.v.).

**TARIJA**. The capital town of the Department of Tarija, Bolivia, on the upper course of the Vermejo, 180 miles south of Sucre, near the border of Argentina, with which it has extensive trade (Map: Bolivia, E 8). The climate is pleasant. Pop., 1914 (est.), 7817.

**TARIK**, tār'ík, IBN ZIAD (?-c.720). The leader of the first Moslem invasion of Spain. He was a Berber, and had been converted to Mohammedanism by the Emir Musa, who made him Governor of Tangier. It was probably on April 30, 711, that Tarik landed at Gibraltar (i.e., *Djebel-Tarik*, the hill of Tarik) with a force of 7000 men. He speedily overran Andalusia, and on July 19, 711, the Visigothic King Roderick (q.v.) was defeated, near Vejer, or Jerez, de la Frontera. Musa, however, became jealous of his successful lieutenant, and joined him in the summer of 712 at Toledo with about 18,000 men. There were frequent quarrels between Musa and Tarik, until finally both were summoned to Damascus by the Caliph Solymán. Musa was disgraced, while of Tarik nothing further is known. Consult U. R. Burke, *History of Spain*, vol. i (New York, 1900), and *Cambridge Medieval History*, vol. ii (ib., 1913).

**TARIM**, tār'ēm'. The principal river of Chinese Turkestan (Map: China, D 3). It rises in the Karakorum Range in the extreme northern part of Kashmir, and flows north, east, and southeast through the great desert basin of Turkestan, emptying into the collection of lakes and marshes known as Lob Nor (q.v.) at the northern base of the Altyn-Tagh. Its length is estimated at over 1000 miles, including the upper course, which is generally called the Yarkand-Darya. After leaving the lofty glaciers of the Karakorum it pierces the Kuen-lun Mountains, and then descends to the plain, where it passes the city of Yarkand. Farther north it receives two large tributaries, the Aksu from the north and the Khotan-Darya from the south, below whose confluence the united stream is known as the Tarim proper. It soon divides into two arms, which flow parallel for a long distance. Receiving no more tributaries, it decreases rapidly in volume by evaporation and by being used for irrigation. As it enters the Lob Nor region, however, the Tarim receives the Chirchik from the Tibetan plateau and another large affluent from the north. Consult Ellsworth Huntington, *The Pulse of Asia* (Boston, 1907), and S. A. Hedin, *Central Asia and Tibet* (New York, 1908).

**TARKINGTON**, (NEWTON) BOOTH (1869- ). An American novelist, born in Indianapolis, Ind., and one of the group of Hoosier (Indiana) writers, which included also, notably, Edward Eggleston and James Whitcomb Riley and Meredith Nicholson. In 1893 he graduated from Princeton University, and thereafter devoted himself chiefly to literature, although in 1903 he served in the Indiana Legislature.

His first published novel, *The Gentleman from Indiana* (1899), is in part a realistic study of life in a small mid-western town, in part a romance. It gained and held popular fancy. *Monsieur Beaucaire* (1900) is a spirited and artistically written little romance of eighteenth-century England. In *The Two Vanrevells* (1902) Tarkington returned to social life in an Indiana town for his setting, portraying it with plenty of romantic sentiment and a dash of melodrama. The short stories *In the Arena* (1905) are studies of American political conditions of the day. In 1905 appeared also *The Conquest of Canaan*, with its very American hero, who lived down a bad reputation and became mayor of his town, and *The Beautiful Lady*, a pleasing romantic trifle with a Parisian setting. Romantic also is his *Guest of Quesnay* (1908), a tale with a strong diffusion of fantasy, and agreeably set in the highways and byways of rural France. *Penrod* (1914) is an amusing and unmerciful, yet withal sympathetic, study of a small boy, and *Seventeen* (1916) treats of a very young man in the same style. *The Turmoil* (1915) is a novel concerned with the influence of a city's industrial progress on its social life. Among other of Tarkington's books are: *Cherry* (1903); *His Own People* (1907); *Beasley's Christmas Party* (1909); *Beauty and the Jacobin* (1911); *The Flirt* (1913). With Harry Leon Wilson (q.v.) Tarkington wrote several plays, including *The Man from Home* (1907); and the dramatized *Monsieur Beaucaire* was produced with great success by Lewis Waller (q.v.). He was elected to membership in the National Institute of Arts and Letters. Consult F. T. Cooper, *Some American Story Tellers* (New York, 1911).

**TÁRLAC**, tār'lák. A province of Luzon, Philippine Islands (Map: Philippine Islands, C 3). Area, 1205 square miles. The eastern part is level, while the western portion comprises the slope of the Cordillera de Cabusilán. The main highway and the railroad traverse the province from north to south. Rice and sugar cane are the principal agricultural products, though some tobacco and corn are raised in the higher altitudes. The forests of the province are of great value; oranges, lemons, and bananas are produced in great variety. The languages are Tagalog, Pampango, and Pangasinán. The capital is Tárlac (q.v.). Pop., 1903, 135,107.

**TÁRLAC**. The capital town of the Province of Tárlac, Luzon, Philippines, on the right bank of the river of the same name, a tributary of the Agno, 73 miles northwest of Manila (Map: Philippine Islands, C 3). It is on the Manila and Dagupán Railroad, and has excellent road connection with surrounding towns. Pop., 1903, 12,340.

**TARLATAN**, tār'lá-tan (probably from Milanese It. *tarlantanna*, linsey-woolsey). A thin, gauzelike fabric of cotton. It is usually dyed or printed in colors, and is often of a rather coarse quality.

**TARLETON**, tār'l'ton, SIR BANASTRE (1754-1833). An English soldier in the American Revolutionary War, born in Liverpool, and educated at Oxford. In 1776 he took part in Clinton's operations against Fort Moultrie (q.v.). Later in the year, under Sir William Erskine, he served in the successful operations in the vicinity of New York, and early in 1777 was with Cornwallis in New Jersey. With the army under Howe, the commander in chief, he took part in the battles of Brandywine and German-

town and the occupation of Philadelphia. In January, 1778, he was promoted captain, and in the following year was made lieutenant colonel of the British legion, a force of cavalry and light infantry, with which he very substantially aided the British cause in the South until the fall of Yorktown in October, 1781. He was an able and intrepid cavalry leader, but gained a reputation for cruelty until Tarleton's quarter came to mean general butchery. Dispatched by Cornwallis, he defeated with great slaughter the superior force of Lieutenant Colonel Buford at Waxhaw Creek, May 29, 1780; he routed a part of General Gates's force at Camden, August 16, and defeated General Sumter at Catawba Fords, August 18. On Jan. 17, 1781 he was defeated by General Morgan at Cowpens. He was with Cornwallis at the final surrender and returned to England in 1782. Representing the opposition, he was elected to represent Liverpool in Parliament in 1790, and there he remained, excepting a brief interruption in 1806-07, until 1812. He was made major general (1794), Governor in Berwick and Holy Island (1808), general (1812), and Baronet (1815). He wrote a *History of the Campaigns of 1780 and 1781 in the Southern Provinces of North America* (1787), a work marred by vanity and partisanship.

**TARLTON, RICHARD** (?-1588). An English comedian of Queen Elizabeth's time. Little is known of his life, but he is said to have been born in Shropshire and to have been at one time keeper of a public house. As an actor he became in 1583 one of the Queen's players who were called the Grooms of the Chamber. A *platt* (or plot) exists of the second part of a play named *The Seven Deadlie Sinns*, as arranged by Tarlton, the dialogue of which was probably largely extemporized. He won such reputation for his constant jesting that his name was attached to many of the witticisms of the day, as well as to ballads and other pieces whose authors thus aimed to profit by his popularity. A collection of jokes called *Tarlton's Jestes* was published a few years after his death; republished as edited by Halliwell for the Shakespeare Society in 1844, with *Tarlton's Newes out of Purgatorie*, which had appeared in 1590, in the form of a message from the dead actor in the other world. He is said to have been the Yorick referred to in *Hamlet*.

**TARN**, tarn. A department of south France, in Languedoc (Map: France, S., G 5). Area, 2231 square miles; pop., 1901, 332,093; 1911, 324,090. The surface is in general elevated and well wooded, and is watered by the river Tarn. In the south and southeast are offshoots of the Cévennes. Coal, iron, copper, and lead are mined and there are lucrative deposits of gypsum and porcelain clay. The vine is extensively cultivated, and there are manufactures of spirituous liquors, woolens, cottons, and silks, iron, leather, and paper. Albi is the capital.

**TARN-ET-GARONNE**, -à-gá'rôn'. A department of south France, formed mainly out of the old Province of Guienne (Map: France, S., F 4). Area, 1441 square miles; pop., 1901, 195,669; 1911, 182,537. The surface is marked by plateaus with an average altitude of 1000 feet, the highest hills not rising above 1600 feet. The principal rivers are the Garonne and its affluents, the Tarn and Aveyron. Cereals are raised in great quantities, and the

grapevine and mulberry are extensively cultivated. Mules and poultry are raised; coal and iron are mined; marble is quarried, and there are manufactures of woolens, linens, silk, iron, cutlery, and beet sugar. Capital, Montauban.

**TARNIER**, tár'nyá', HÉPHANE (1828-97). A French gynecologist. Born at Aiserey (Côte-d'Or), he received his medical education at Paris, where he became agrégé and chief gynecologist of the Hôpital de la Maternité in 1867. In 1884 he succeeded Pajot in the Ecole de Médecin, and in 1888 was appointed professor of gynecology of the Faculté de Médecin at Paris. In 1892 he became a member of the Academy of Medicine, whose president he was in 1891, and in 1892 he was elected president of the Obstetrical Society, which he had helped to found. Tarnier was one of the leading French gynecologists of his time, especially successful in his fight against puerperal fever. His best-known work is *Traité de l'art des accouchements* (1878-1901).

**TARNOPOL**, tár'nó-pól. A town of Galicia, Austria, 76 miles east-southeast of Lemberg, on the Sereth (Map: Austria, J 2). Among the industrial establishments are refineries for spirits, breweries, and steam mills. It suffered severely during the Russian invasions in 1914 and 1915. (See WAR IN EUROPE.) Pop. (commune), 1910, 33,853, about half Poles and half Jews.

**TARNOW**, tár'nów. A town of Galicia, Austria, 137 miles west of Lemberg, on the Dunajec, near its confluence with the Biala (Map: Austria, G 1). The chief manufactures are of agricultural implements; there are steam, flour, and saw mills. Tarnow was captured but later evacuated by the Russians in the Great War which began in 1914. (See WAR IN EUROPE.) Pop. (commune), 1900, 33,974; 1910, 36,731.

**TARNOWSKI**, tár-nófski, STANISLAV, COUNT (1837- ). A Polish historian of literature, born at Dzikov, Galicia. He studied in Cracow and Vienna, spent nearly two years in confinement because implicated in the revolt of 1863, was elected to the Galician Diet and the Austrian Reichsrat in 1867, and subsequently devoted himself entirely to literary studies. In 1871 he was appointed professor of Polish literature at the University of Cracow. In 1885 he became a member of the Austrian House of Lords, and in 1890 president of the Cracow Academy of Sciences. With Szujski he established the conservative *Przeglad Polski*, in which he published many of his literary monographs, distinguished by thoroughness, keen judgment, and elegance of style. His writings include essays *On the Polish Novel in the Nineteenth Century* and *On the Decadence of Polish Literature in the Eighteenth Century*, *On the Comedies of Fredro*, *Schiller's Dramas*, *Shakespeare in Poland*, but his principal works are *Studies in the History of Polish Literature* (1886-92) and *History of Polish Literature*, in six volumes (*Historia literatury polskiej*, Cracow, 1900 et seq.).

**TARO**, tá'ró (Polynesian name), or **TARA** (*Colocasia antiquorum esculenta*). A plant of the family Araceæ, cultivated for its roots, which are a leading article of food in the South Sea Islands. The tuberous roots, which are from 12 to 16 inches in length, are washed to remove their acidity and boiled or roasted, the rind being first scraped off. In Hawaii the

cooked root is fermented, the product being called poi. The young leaves are used like

TARO (*Colocasia antiquorum esculenta*).

spinach and the young shoots like asparagus. See COCCO; ELEPHANT'S EAR.

**TARPAN**, tär'pän. The Mongolian name for the wild ass, kiang, or dziggetai, of the high plateaus of Central Asia. See ASS.

**TARPEIA**. See TARPEIAN ROCK.

**TARPEIAN** (tär-pē'yan) **ROCK** (Lat. *Rupes Tarpeia*). A portion of the southern part of the Capitoline Hill in Rome. (See CAPITOL.) According to tradition, in the time of Romulus, Tarpeia, daughter of Tarpeius, governor of the Roman citadel on the Capitoline, covetous of the golden ornaments of the Sabine soldiery, and tempted by their consent to give her what they wore on their left arms, opened a gate of the citadel to the Sabine King, Titus Tatius, who had come to avenge the rape of the Sabine women. The Sabines crushed Tarpeia to death beneath their shields, and she was buried in the part of the hill which bears her name. From early times criminals were frequently put to death by being hurled from the Tarpeian rock. Consult the article "Tarpeius," in Friedrich Lübker, *Reallexikon des klassischen Altertums* (8th ed., Leipzig, 1914).

**TAR/PON** (from the North American Indian name), or TARPUM. A great herring-like fish (*Tarpon atlanticus* or *Megalops thrissoides*) of the West Indies and neighboring waters, which, with a few other species scattered about the tropical world, represents the isospondylous family Elopidae. This fish is regarded by many anglers as affording sport with a rod and line superior to that given by any other fish. The tarpon (see Colored Plate of AMERICAN GAME FISHES, accompanying article TROUT) has something the shape of a salmon, and great power in swimming and leaping. It is often 6 feet in length and may weigh 100 pounds. It preys upon other fishes and small fry. The flesh is poor and not much valued as food, but the great silvery cycloid scales are much used in ornamental work. Another species of the family (*Elops saurus*) is about half as large; it is abundant about all tropical coasts, and is known under a great variety of names.

**TARPON FISHING**. The sport of angling

for tarpon (q.v.) with rod and line is the most skillful and exciting which America affords. The angler goes in a small boat some distance from shore, with an experienced man to row it, and uses a heavy rod, 7½ to 8 feet long, with a multiplying reel, 200-250 yards of linen line, and a spoon bait. When a fish weighing perhaps 100 pounds seizes this, and begins those rushes and mighty leaps which have given the silver king the just title of greatest of game fishes, the power and science of the angler are both tested in the highest degree. Excellent tarpon fishing may usually be obtained all around the southern coast of Florida and its reefs; and also along the coast of Texas. Consult American books mentioned under FISH; and ANGLING.

**TARQUIN'II**. The name of an ancient Etruscan city. See CORNETO.

**TARQUINIUS**. The family name of two kings of Rome. With the legends regarding them, the fortunes of the city are closely interwoven. 1. Demaratus, a Corinthian noble, emigrated to Tarquinii, in Etruria, where he married an Etruscan wife. A son, Lucumo, married into a noble Etruscan family, and emigrated to Rome, where he was hospitably received and soon after admitted to the rights of citizenship, as Lucius Tarquinius Priscus. The Roman monarch, Ancus Marcius, appointed him guardian of his children; on the death of Ancus (616 B.C.), the Senate and the citizens unanimously elected Tarquinius to the throne. He forced the 12 sovereign cities of Etruria to recognize his supremacy. To him also are ascribed the construction of the magnificent cloacæ, or sewers; the laying out of the Circus Maximus; the building of shops (*tabernæ veteres*) adjoining the Forum; the institution of the Great or Roman Games; and the foundation of the Capitoline temple. He was assassinated in 578 B.C., at the instigation of the sons of Ancus Marcius, who considered themselves entitled to the throne. Their crime did not avail them, for Servius Tullius was elected to the vacant throne. 2. LUCIUS TARQUINIUS SUPERBUS, son of (1), having murdered his father-in-law, Servius Tullius (q.v.), is represented as audaciously usurping the throne (534 B.C.); but as the whole drift of his legislative policy was to abolish the reforms of Servius, the real significance of this part of his career lies in the fact that it indicates a successful reaction, on the side of the patricians, against the more liberal and progressive policy of the preceding age. That the younger Tarquinius, at least, is an historical character, seems to be pretty generally allowed. By intrigues he obtained or consolidated the Roman hegemony in Latium. He offered sacrifice in the name of all the Latins at the Alban Mount; fused the contingents of the Latins with the Roman legion; put to death as traitors such of their chiefs as opposed him; and, at the head of the combined forces, successfully attacked the Volscians. On his return he completed the building of the temple of Jupiter Capitolinus, which the elder Tarquinius had begun, and deposited in the vaults the Sibylline Books. (See SIBYL.) But his lavish expenditure both in war and peace necessitated the imposition of heavy taxes, and the patience both of plebs and patricians was beginning to give way. During a war against the Rutuli Tarquinius laid siege to the town of Ardea. Here in the Roman camp occurred

the famous dispute between Sextus Tarquinius, the son of the King, and Collatinus, about the virtues of their respective wives, which led to the rape of Lucretia (q.v.). L. Junius Brutus (q.v.) carried the news of the outrage to Rome and called upon the people to rise against the tyrant, who was deposed by the Senate; finally, the army before Ardea revolted, Tarquinius and his sons were obliged to flee, and an aristocratic republic was constituted at Rome (509 B.C.). Three different attempts were made to restore Tarquinius by force: first, by his own Etruscan kinsmen of Tarquinii; second, by Lars Porsena (q.v.) of Clusium; third, by his son-in-law, Octavius Mamilius. All these, according to the legend, failed; and at length Tarquinius, utterly beaten, retired to Cumæ, where he died. The expulsion of the Tarquinius has been interpreted as a revolt of Romans and Sabines against Etruscan domination of Rome. Consult: Livy, i, 34-41, 46-60; Dionysius of Halicarnassus, iii, 46-73, v, i-vi, 21; Sir G. C. Lewis, *Credibility of Early Roman History* (London, 1855); W. Ihne, *Early Rome*, vol. i (New York, 1878); E. Pais, *Storia di Roma*, vol. i (Rome, 1898); id., *Storia critica di Roma*, vol. i (ib., 1913); and the article "Tarquinius" in Friedrich Lübker, *Reallexikon des klassischen Altertums* (8th ed., Leipzig, 1914).

**TARR, RALPH STOCKMAN** (1864-1912). An American geographer, born at Gloucester, Mass. He was educated at Lawrence Scientific School, Harvard, and after 1897 was professor of dynamic geology and physical geography at Cornell, where he had been an assistant professor for five years. Besides acting as associate editor of the *Bulletin of the American Geographical Society* and the *Journal of Geography*, he published: *Economic Geology of the United States* (1893); *Physical Geography of New York State* (1902); *New Physical Geography* (1903); *Geography of Science* (1905), with C. A. McMurry; and the posthumous *College Physiography* (1914) and *Alaskan Glacier Studies* (1914), with Lawrence Martin. Tarr contributed to the NEW INTERNATIONAL ENCYCLOPEDIA.

**TARRAGON, tär'ä-gön.** A garden herb. See ARTEMISIA.

**TARRAGONA, tär'rä-gō'nä** (Lat. *Tarraco*). A seaport of Spain, capital of the province of the same name, in Cataluña, situated on the Mediterranean at the mouth of the Francolí, 63 miles southwest of Barcelona (Map: Spain, F 2). On the land side it is bordered by the beautiful Campo de Tarragona, whose agricultural products form an important part of its trade. The local industries embrace manufactures of alcohol, liquors, soap, flour, silks, paper, and salted fish. Since 1892 it has been an important port of entry. The town contains a normal school for both sexes, a museum of archaeology, and several hospitals. The nucleus of the old city is situated on a steep hill, now crowned by the cathedral and the Bishop's Palace. Pop., 1900, 26,281; 1910, 23,289. The city was probably founded as a Greek colony. Under the Romans it enjoyed a prominent position from the time of the Scipios, being at one time a residence of Augustus. It gave its name to the Province of Hispania Tarraconensis. From this period still survive a portion of the ancient wall, with cyclopean remains, an amphitheatre, the ruins of the palaces of Augustus and of Pontius Pilate, and an aqueduct still in

use. The city was destroyed by the West Goth Euric (475). It was taken by the Arabs in 713 and partially destroyed, but was restored by Abd ur Rahman (780). In the twelfth century it was taken by the Christians and became an archiepiscopal see. In 1811 it underwent a siege and sack by the French under Suchet.

**TARRASA, tär-rä'sä.** A town in the Province of Barcelona, in Cataluña, Spain, 22 miles northwest of the city of Barcelona, on the Barcelona-Lérida line of the Northern Railway. It is an important industrial centre, with manufactures of cotton and woolen cloths. The Romanesque churches of San Pedro and San Miguel date from the Christian reconquest, but most of its structures are modern, including a large royal college, industrial schools, chamber of commerce, and two theatres. Pop., 1900, 15,872; 1910, 22,679.

**TARRASCH, tär'räsh, SIEGBERT** (1862- ). A German chess master, born in Breslau. He studied medicine at Berlin and Halle, and practiced his profession in Nuremberg, where in 1883 he won his mastership in chess. His success in chess continued, and at the international tournaments in Breslau (1889), Manchester (1890), and Dresden (1892), he won the first prize with only a single game lost. At the tournament held in 1898 at Vienna he tied with the American, Pillsbury, for first prize, winning on the play-off; was sixth at the International Masters' Tournament held at Monte Carlo in 1903, and again won first place in the tournament at Ostend in 1907. He became distinguished for careful play and ingenious combinations. He published: *300 Schachpartien, gespielt und erläutert von Tarrasch* (1894); *Der Schachwettkampf Marshall-Tarrasch* (1897); *Das Champion-Turnier zu Ostende* (1907); *Das Grossmeisterturnier zu St. Petersburg im Jahre 1904* (1914).

**TARRYTOWN.** A village in Westchester Co., N. Y., 25 miles north of New York City; on the east side of Tappan Bay, an expansion of the Hudson River, and on the New York Central Railroad (Map: New York, B 2). It is situated on ground rising from the river and is a residential place. The vicinity of the village, which has been made famous by Washington Irving (see SLEEPY HOLLOW), is of great interest because of its connection with the history of the Revolutionary period. Irving's burial place is in Sleepy Hollow Cemetery, about three-fourths of a mile north of the village. The Dutch Church, dating from 1685, and the Philippe Manor House, built from 1683, are the most noteworthy of the older buildings. Other features of Tarrytown include Miss Mason's School, familiarly known as the Castle, the Tarrytown Lyceum, the Institution of Mercy (Roman Catholic), and Irving Institute. Drill and automobile works are the leading industrial establishments. Pop., 1900, 4770; 1910, 5600.

The name Tarrytown is derived from the Dutch word *terwen*, meaning wheat, on account of the quantity of that grain raised in the neighborhood. In 1683 Vredryk Flypse (Frederick Philipse) moved here and 10 years later secured manorial rights to the adjacent territory. Major André was captured here on Sept. 23, 1780. About two miles south of the village, at Irvington, is Sunnyside, the home of Washington Irving. Consult E. M. Bacon, *Chronicles of Tarrytown and Sleepy Hollow* (New York,

1897), and H. W. Mabie, "Tarrytown," in L. P. Powell (ed.), *Historic Towns of the Middle States* (ib., 1899).

**TARSHISH**, tär'shish. According to the Old Testament, a region which was the resort of Phœnician commerce, and the source of valuable mineral products. The earliest mention is in Genesis, x. 4, where it is associated with lands probably identical with Crete, Cyprus, and Rhodes. Its special trade was with Tyre, which seems to have been there a colonial factory (cf. Isa. xxii; Ezek. xxvii. 12, 25). Certain texts, however, seem to oppose this western location. "Ships of Tarshish" are mentioned as starting from Solomon's port at Ezion-geber (q.v.) on the Red Sea (1 Kings x. 22; xxii. 48); while the Chronicler (2 Chron. ix. 21; xx. 36-37) makes them go to Tarshish from that point. Hence has arisen the view that the Hebrews and Phœnicians circumnavigated Africa, or else that there was an Oriental land of Tarshish in addition to the Occidental one. Ship of Tarshish, however, is now generally supposed to mean some kind of large vessel designed for distant voyages. Tarshish is, as a rule, identified with the Tartessus of Herodotus (iv, 152), Strabo (ii, 158), and other Greeks, at the mouth of the Guadalquivir, near Cadiz; and the southern part of Spain in general is largely accepted as the region of Tarshish. The location in Spain would agree with the products assigned to Tarshish, silver, iron, lead, while the tin may have been brought thither from the British Isles. Also the jewel called the stone of Tarshish, or simply a tarshish (translated beryl in Ex. xxviii. 20, and elsewhere), may represent one of the numerous precious stones found in Spain. See OPHIR. Consult: Z. Bochart, *Geographia Sacra* (Caen, 1646); A. Ritter, *Comparative Geography*, vol. i (Eng. trans., Edinburgh, 1886); Hugo Winckler, *Forschungen*, vol. i (Leipzig, 1893); T. K. Cheyne and W. M. Müller, in *Orientalische Literaturzeitung*, vol. iii (Leipzig, 1900); Johannes Dahse, "Ein zweites Goldland Salomos," in *Zeitschrift für Ethnologie*, vol. xliii (Berlin, 1911).

**TARSIA**, tär'sè-à, or **INTARSIA** (It., from Lat. *inserere*, to insert, equivalent to the Eng. *inlay* and the Fr. *marquetry*). Tarsia is the term applied particularly to Italian inlays of the fourteenth, fifteenth, and sixteenth centuries. Consult F. H. Jackson, *Intarsia and Marquetry* (London, 1903). See INLAY; MARQUETRY.

**TARSIER**, tär'si-ër (Fr. *tarsier*, from Neo-Lat. *Tarsius*, from *tarsus*, from Gk. *ῥαρός*, board surface), or **MALMAG**. A genus of small East Indian animals (*Tarsius*), closely related to the lemurs, but set apart in a family Tarsiidae, which inhabit trees in the Malayan and Philippine Archipelago and have the general habits of lemurs. Seven species are recognized. The best known of these, *Tarsius philippensis*, is confined to the islands of Samar and Mindanao, is nowhere common, is nocturnal, and feeds upon insects and small reptiles. In size it is about as large as a rat, has a large, broad

head, with very large eyes, teeth of a generalized type, very long half-naked hind legs and short forelegs, and the long bony toes end in large pads beneath the terminal joints. The tail is long and tufted at the end. It moves by long leaps from bough to bough. The wide-spread scientific name *Tarsius spectrum* is undeterminable. Cf. GALAGO and MOUSE LEMUR; and consult authorities and Plate under LEMUR.

**TARSIPES**, tär'si-péz. See PHALANGER.

**TAR'SUS** (Lat., from Gk. *ῥαρός*, *Tarsos*, *ῥαρόν*, *Tarsoi*). The chief city of ancient Cilicia (q.v.), and of eastern Asia Minor, situated on both sides of the navigable river Cydnus, in the midst of a beautiful and productive plain, about 10 miles from the sea (Map: Turkey in Asia, C 3). Tarsus commanded the pass over Mount Taurus, the Cilician Gates, which formed the only means of communication with northern and western Asia Minor, and in almost equal measure the route to northern Syria and the East by the Amanian or Syrian Gates. The first mention of the place as Tarzi is on the Black Obelisk of Shalmaneser II, about the middle of the ninth century B.C., where its capture by the Assyrians is recorded. It was the capital of the Kingdom of Cilicia, which was long ruled, under Persian suzerainty, by a line of kings who bore the hereditary name of Syennesis, and later was the residence of a Persian satrap. With the conquest of Alexander the Great, it passed into Greek hands, and during the following period was usually in the power of the Seleucidæ of Syria. At the end of that century it passed under the Roman supremacy, and upon the organization of the Province of Cilicia (64 B.C.) it became the capital of that province. Later, Mark Antony made it a free city; here in 38 B.C. he was visited by Cleopatra. Under the Empire the free city seems to have enjoyed a popular form of government with a property qualification for the franchise. This gives additional point to the claim of the Apostle Paul—a native of this place—to be a citizen of Tarsus, as that implied a certain social position. All Cilicia passed under the control of the Arabs in 660 A.D. In 964-966 Nicephorus II Phocas (q.v.) conquered Cilicia for the Byzantine Empire. Tarsus was a place of consequence even in Byzantine times, but suffered from its proximity to the Syrian frontier. In the eleventh to the thirteenth century the city formed a part of Lesser Armenia. About the beginning of the sixteenth century it passed under Turkish control. The modern town, though large, with a population of about 25,000, is dirty and mean, containing no vestige of its ancient splendor, and but few visible ancient ruins. The most conspicuous ruin is the large concrete foundation of a Roman building, popularly called the Tomb of Sardanapalus. Consult W. M. Ramsay, "Cilicia, Tarsus, and the Great Taurus Pass," in *Geographical Journal* (London, 1903), and id., *Cities of St. Paul* (New York, 1907).
